Appendix B-2: Consent Order – C.P. Crane Generating Station ... pages 1759-1763

**Appendix B-1: Consent Order – Brandon Shores and Wagner Generating Stations**

**IN THE MATTER OF:**

**RAVEN POWER  
FORT SMALLWOOD LLC  
1005 Brandon Shores Road  
Baltimore, Maryland 21226**

**\* BEFORE THE AIR AND  
\* RADIATION  
\* ADMINISTRATION  
\* OF THE MARYLAND  
\* DEPARTMENT  
\* OF THE ENVIRONMENT  
\*  
\***

**\* \* \* \* \***

**CONSENT ORDER**

The Maryland Department of the Environment (“Department”) and Raven Power Fort Smallwood LLC (“Raven Power”) hereby represent and acknowledge that they enter into this Consent Order regarding emissions at the Fort Smallwood electric generating complex, consisting of the Brandon Shores and Herbert A. Wagner electric generating stations, as they relate to the Anne Arundel County and Baltimore County 1-Hour Sulfur Dioxide (“SO<sub>2</sub>”) Non-Attainment Area.

**RECITATIONS**

WHEREAS, Raven Power owns and/or operates the Fort Smallwood electric generating complex, located at 1005 Brandon Shores Road in Baltimore, Maryland 21226 and composed of the Brandon Shores and H.A. Wagner electric generating stations (“Fort Smallwood Complex”); and

WHEREAS, on or about January 1, 2017, the Department issued to Raven Power a Part 70 Operating Permit, Permit No. 24-003-0468 (the “Operating Permit”), governing emissions to the ambient atmosphere from the operation of the Fort Smallwood Complex; and

WHEREAS, the Fort Smallwood Complex, in relevant part, burns coal in four fossil

fuel fired steam boilers (Brandon Shores Units BS1 and BS2, and H.A. Wagner Units W2 and W3) and burns oil in two fossil fuel fired steam boilers (H.A. Wagner Units W1 and W4) in order to generate electric energy for commercial sale. The burning of coal and oil at the Fort Smallwood Complex results in the emission of SO<sub>2</sub> to the ambient atmosphere; and

WHEREAS, on or about June 30, 2016 (effective September 12, 2016), the United States Environmental Protection Agency (“EPA”) designated the area within 28.6 kilometers around Unit W3 of the H.A. Wagner electric generating station as a nonattainment area under the 1-Hour SO<sub>2</sub> National Ambient Air Quality Standard (“NAAQS”) (“SO<sub>2</sub> Nonattainment Area”). The Fort Smallwood Complex is within the SO<sub>2</sub> Nonattainment Area; and

WHEREAS, pursuant to its obligations under § 172 of the federal Clean Air Act, 42 U.S.C. § 7502, the State of Maryland is required to submit to the EPA, for its review and approval, a State Implementation Plan (“SIP”) designed to reduce SO<sub>2</sub> emissions such that the SO<sub>2</sub> levels in the SO<sub>2</sub> Nonattainment Area will not exceed the 1-Hour SO<sub>2</sub> NAAQS; and

WHEREAS, a nonattainment SIP may include voluntary emissions reductions from sources of pollutants, so long as the voluntary reductions are made federally enforceable; and

WHEREAS, pursuant to §§ 2-103 and 2-604 of the Environment Article, Annotated Code of Maryland, the Department has jurisdiction over emissions into the air and may

issue corrective orders to address violations of ambient air quality requirements in the State;  
and

WHEREAS, notwithstanding the Fort Smallwood Complex's contributions to the SO<sub>2</sub> Nonattainment Area, the Department acknowledges that the Fort Smallwood Complex has not violated the provisions governing SO<sub>2</sub> emissions in the Code of Maryland Regulations or the Operating Permit; and

WHEREAS, Raven Power and the Department wish to enter into this Consent Order, the provisions of which will be incorporated into Maryland's SIP and the Operating Permit, to establish federally enforceable emissions limits designed to help attain the 1-Hour SO<sub>2</sub> NAAQS in the SO<sub>2</sub> Nonattainment Area.

#### **ORDER**

NOW THEREFORE, pursuant to § 2-604 of the Environment Article, Annotated Code of Maryland, the Department hereby **ORDERS**, and Raven Power hereby **CONSENTS** to the following:

#### **EMISSIONS LIMITS**

1. Beginning January 1, 2021, at all times when Unit BS1 and/or BS2 at the Brandon Shores generating station (whether operating individually or in tandem) and Unit W3 at the H.A. Wagner generating station are simultaneously operating, the following SO<sub>2</sub> emissions limits shall apply:

- a. Units BS1, BS2, and W3 shall not exceed a cumulative SO<sub>2</sub> emissions limit of 3,860 pounds per hour, as measured on a 30-day rolling average,

including only those hours when the applicable units are operating; and

- b. Units BS1 and BS2 (operating either individually or in tandem) shall not exceed a cumulative total of 435 hours per calendar year when the applicable units are operating at a combined SO<sub>2</sub> emissions rate greater than 2,851 pounds per hour.

2. Beginning January 1, 2021, at all times when operating, Unit BS1 and BS2 at the Brandon Shores generating station (whether operating individually or in tandem) shall not exceed a combined SO<sub>2</sub> emissions limit of 3,860 pounds per hour, as measured on a 30-day rolling average.

3. Beginning January 1, 2021, at all times when operating, Unit BS1 and BS2 at the Brandon Shores generating station (whether operating individually or in tandem) shall not exceed a combined SO<sub>2</sub> emissions limit of 9,980 pounds per hour, as measured on a rolling three-hour average.

4. Beginning January 1, 2021, at all times when Unit W3 at the H.A. Wagner generating station is not operating, Unit BS1 and BS2 at the Brandon Shores generating station (whether operating individually or in tandem) shall not exceed a combined SO<sub>2</sub> emissions limit of 5,150 pounds per hour, as measured on a 1-hour average, on more than three hours per calendar year.

5. Beginning January 1, 2021, at all times when operating, Unit W1 at the H.A. Wagner generating station shall not exceed an SO<sub>2</sub> emissions limit of 480 pounds per hour, as measured on a one-hour average.

6. Beginning January 1, 2021, at all times when operating, Unit W1 at the H.A. Wagner generating station shall not exceed 438 hours of operation per calendar year when burning fuel oil.

7. No later than July 1, 2020, Unit W2 at the H.A. Wagner generating station shall permanently cease burning coal and shall only burn natural gas.

8. Beginning January 1, 2021, at all times when operating, Unit W3 at the H.A. Wagner generating station shall not exceed an SO<sub>2</sub> emissions limit of 1,904 pounds per hour, as measured on a 30-day rolling average.

9. Beginning January 1, 2021, at all times when operating, Unit W3 at the H.A. Wagner generating station shall not exceed a maximum rate of 3,289 pounds SO<sub>2</sub> per hour, as measured on a one-hour average.

10. Beginning January 1, 2021, at all times when operating, Unit W3 at the H.A. Wagner generating station shall not exceed a cumulative total of 336 hours per calendar year when the Unit's SO<sub>2</sub> emissions rate is greater than 2,299 pounds per hour, as measured on a one-hour average.

11. Beginning January 1, 2021, at all times when operating, Unit W4 at the H.A. Wagner generating station shall not exceed an SO<sub>2</sub> emissions limit of 1,350 pounds per hour, as measured on a one-hour average.

12. Beginning January 1, 2021, at all times when operating, Unit W4 at the H.A. Wagner generating station shall not exceed 438 hours of operation per calendar year when burning fuel oil.

### COMPLIANCE MECHANISM

13. Raven Power will demonstrate compliance with the limitations of Paragraphs 1 through 12 through quarterly reports utilizing calculation methodologies, continuous emissions monitoring system (CEMS) availability requirements, and a report format approved by the Department. Raven Power shall submit the proposed methodologies, CEMS availability requirements, and report format within 6 months of the effective date of this consent order for approval by the Department. Raven Power shall submit each quarterly report within 30 days of the end of the applicable quarter.

14. For the purposes of Paragraphs 1-12, which require the calculation of emissions rates, an emissions rate shall be calculated as the sum of the SO<sub>2</sub> hourly emissions (lbs) of all the applicable units during the applicable period, divided by the sum of the operating hours during the applicable period. "Operating hour" is defined as any hour or portion of an hour that a unit combusts fossil fuel.

### CONTINGENCY MEASURES

15. Raven Power shall comply with the following contingency measures, which are a required component of the nonattainment SIP revision pursuant to Section 172(c)(9) of the Clean Air Act.

16. At any time that emissions from BS1, BS2, and/or W3 at the Fort Smallwood Complex exceed one or more of the SO<sub>2</sub> emissions limits or fuel oil operations limits identified in Paragraphs 1 through 12 of this Consent Order, Raven Power shall, with 48

hours of such exceedance, undertake a full-system audit of Units BS1, BS2, W1, W2, W3, and W4 (cumulatively) at the Fort Smallwood Complex and shall submit a telephone report on the next business day and a written report to the Department within 10 days of the exceedance. At any time that emissions from Units W1, W2, and/or W4 at the Fort Smallwood Complex exceed one or more of the SO<sub>2</sub> emissions limits or fuel oil operations limits identified in Paragraphs 1 through 12 of this Consent Order, Raven Power shall, within 48 hours of knowledge of fuel test results, undertake a full-system audit of Units BS1, BS2, W1, W2, W3, and W4 (cumulatively) at the Fort Smallwood Complex and shall submit a telephone report on the next business day and a written report to the Department within 10 days of the exceedance. The telephone report shall be submitted pursuant to COMAR 26.11.01.07C. A written report to satisfy this requirement shall include both (1) the results of the full-system audit, and (2) a report of excess emissions prepared pursuant to COMAR 26.11.01.07D and Section 3.4 of the Operating Permit. The full-system audit shall consist of a review of the parameters routinely monitored by the continuous emissions monitoring systems and the digital data acquisition systems installed on the SO<sub>2</sub> generating units and their control devices and programs to determine whether or not the units and their controls were operating in accordance with good engineering practices.

- a. If the units or their controls were not operating in accordance with good engineering practices, then Raven Power shall implement corrective actions to ensure that the limits of this Consent Order are not exceeded.
- b. If the units and controls **were** operating in accordance with good

engineering practice, then Raven Power shall inform the Department as to the reasons for their exceedance of one or more of their SO<sub>2</sub> emissions limits and implement corrective actions to ensure that the limits of this Consent Order are not exceeded.

- c. In any case of an exceedance of an SO<sub>2</sub> emission limit or of a fuel oil operations limit, Raven Power shall document and notify the Department of the corrective actions that they have taken.
- d. The audit, report of excess emissions, documentation of corrective actions taken, and associated records shall be maintained on site for five years.

17. If the Essex, Maryland monitor (AIRS ID 24-005-3001) or any other Department-approved air quality SO<sub>2</sub> monitor located within the SO<sub>2</sub> Nonattainment Area, measures a 1-hour SO<sub>2</sub> concentration exceeding 75 parts per billion (i.e. an exceedance of the 1-hour SO<sub>2</sub> NAAQS), then the Department will notify Raven Power within 5 business days both verbally and in writing. If, however, Raven Power first notifies the Department both verbally and in writing of the monitored exceedance, then the Department will not also notify Raven Power. In either case, whether it is the Department or Raven Power who first notifies the other party of the monitor's exceedance of the 75 parts per billion SO<sub>2</sub> limit, within 2 business days of that first notification, Raven Power shall notify the Department whether Units BS1, BS2, W1, W2, W3, and W4 were running at the time of the exceedance or within 24 hours preceding the exceedance. If any of those Units were running during that timeframe, Raven Power shall analyze the meteorological data on the day the 1-hour

exceedance occurred to determine the extent the Fort Smallwood SO<sub>2</sub> emissions contributed to the 1-hour exceedance. The meteorological data analysis shall include: (1) trajectories run at three different heights (one at stack height; and two more within the boundary layer) by the National Oceanic and Atmospheric Administration's Hysplit program or an equivalent program; and (2) an analysis of meteorological data including the Baltimore-Washington International Airport's meteorological data and modeled upper air data using the National Weather Service's Bufrkit or an equivalent program. Raven Power shall submit its meteorological data analysis, and its findings there from, to the Department within 30 days of written notification of the exceedance of the 1-hour SO<sub>2</sub> NAAQS.

#### INCORPORATION OF REQUIREMENTS

18. The Department intends to submit this Consent Order to the EPA for inclusion in the Maryland SIP. Raven Power agrees that it will not object to a revision of the Maryland SIP that incorporates the SO<sub>2</sub> emissions limits and contingency measures of this Consent Order. Upon renewal of the Operating Permit, the Department shall incorporate the SO<sub>2</sub> emissions limits, compliance mechanisms, and contingency measures of this Consent Order into the federally enforceable portion of the Operating Permit pursuant to COMAR 26.11.03.20A(1)(d). Raven Power further agrees that it shall not object to incorporation of the SO<sub>2</sub> emissions limits, compliance mechanisms, and contingency measures of this Consent Order into the Operating Permit.

IN WITNESS WHEREOF, this Consent Order is agreed to, and the terms and conditions herein consented to, as evidenced by the parties' respective signatures affixed

below as of the day and year written.

IN THE MATTER OF:

C.P. CRANE LLC  
251 Little River Drive  
Wilmington, Delaware 19808

\* BEFORE THE AIR AND  
\* RADIATION  
\* ADMINISTRATION  
\* OF THE MARYLAND  
\* DEPARTMENT  
\* OF THE ENVIRONMENT  
\*  
\*

\* \* \* \* \*

**CONSENT ORDER**

The Maryland Department of the Environment (hereinafter “the Department” or “MDE”) and C.P. Crane LLC hereby represent and acknowledge that they enter into this Consent Order regarding emissions at the C.P. Crane electric generating station as they relate to the Anne Arundel County and Baltimore County 1-Hour Sulfur Dioxide (“SO<sub>2</sub>”) Non-Attainment Area.

**RECITATIONS**

WHEREAS, C.P. Crane LLC owns and operates the C.P. Crane electric generating station, located at 1001 Carroll Island Road in Middle River, Maryland 21220 (“Crane Generating Station”); and

WHEREAS, on or about June 1, 2016, the Department issued to C.P. Crane LLC Part 70 Operating Permit, Permit No. 24-005-0079 (the “Operating Permit”), governing emissions to the ambient atmosphere from the operation of the Crane Generating Station; and

WHEREAS, the Crane Generating Station, in relevant part, burns coal in two fossil-fuel fired cyclone burner steam boilers in order to generate electric energy for commercial sale. The burning of coal at Unit 1 and Unit 2 of the Crane Generating

Station results in the emission of SO<sub>2</sub> to the ambient atmosphere; and

WHEREAS, on or about June 30, 2016, the United States Environmental Protection Agency designated the area within 28.6 kilometers around Unit W3 of the H.A. Wagner electric generating station as a nonattainment area under the 1-hour SO<sub>2</sub> National Ambient Air Quality Standard ("NAAQS") ("SO<sub>2</sub> Nonattainment Area"). The Crane Generating Station is within the SO<sub>2</sub> Nonattainment Area; and

WHEREAS, pursuant to its obligations under § 172 of the federal Clean Air Act, 42 U.S.C. § 7502, the State of Maryland is required to submit to the EPA, for its review and approval, a State Implementation Plan ("SIP") designed to reduce SO<sub>2</sub> emissions such that the SO<sub>2</sub> levels in the SO<sub>2</sub> Nonattainment Area will not exceed the 1-Hour SO<sub>2</sub> NAAQS; and

WHEREAS, a nonattainment SIP may include voluntary emissions reductions from sources of pollutants, so long as the voluntary reductions are made federally enforceable; and

WHEREAS, pursuant to §§ 2-103 and 2-604 of the Environment Article, Annotated Code of Maryland, the Department has jurisdiction over emissions into the air and may issue corrective orders to address violations of ambient air quality requirements in the State; and

WHEREAS, notwithstanding the Crane Generating Station's contributions to the SO<sub>2</sub> Nonattainment Area, the Department acknowledges that the Crane Generating Station has not violated the provisions governing SO<sub>2</sub> emissions in the Code of Maryland

Regulations or the Operating Permit; and

WHEREAS, C.P. Crane LLC and the Department wish to enter into this Consent Order, the provisions of which will be incorporated into Maryland's SIP and the Operating Permit, to establish federally enforceable emissions limits designed to help attain the 1-Hour SO<sub>2</sub> NAAQS in the SO<sub>2</sub> Nonattainment Area.

### **ORDER**

NOW THEREFORE, pursuant to § 2-604 of the Environment Article, Annotated Code of Maryland, the Department hereby **ORDERS**, and C.P. Crane LLC hereby **CONSENTS** to the following:

#### **EMISSIONS LIMIT**

1. At all times, Unit 1 and Unit 2 (the "Units") at the Crane Generating Station (whether operating individually or in tandem) shall not exceed a combined SO<sub>2</sub> emissions limit of 2,900 pounds per hour, as measured on a 1-hour average.

#### **COMPLIANCE MECHANISM**

2. C.P. Crane LLC has disabled the Units and C.P. Crane LLC agreed to permanently cease the burning of coal in the Units under a previous Consent Order executed with the Department. As such, C.P. Crane LLC will notify the Department (1) upon implementation of any plan to restart coal burning operations at either Unit 1 or Unit 2 and (2) of any change in the inoperable status of the Units within 48 hours of the change.

3. Should a change in status to the Units occur that affects the SO<sub>2</sub> emission

limits of the units then C.P. Crane LLC will demonstrate compliance with the limitation of Paragraph 1 through reports utilizing calculation methods approved by the Department.

4. For the purposes of calculating a combined emissions rate pursuant to Paragraph 1, C.P. Crane LLC shall document each unit's hourly emissions rate, as calculated on a 1-hour average. A combined hourly emissions rate shall be calculated as the sum of each applicable unit's hourly average emissions (lbs) during the applicable period.

5. Compliance with the SO<sub>2</sub> emissions limit of Paragraph 1 shall be measured using a continuous emissions monitoring system installed, maintained, and operated in accordance with COMAR 26.11.01.011 and 40 CFR Part 75.

#### INCORPORATION OF REQUIREMENTS

6. The Department intends to submit this Consent Order to the U.S. Environmental Protection Agency for inclusion in the Maryland State Implementation Plan. C.P. Crane LLC agrees that it will not object to a revision of the Maryland State Implementation Plan that incorporates the SO<sub>2</sub> emissions limits of this Consent Order. Upon renewal of the Operating Permit, the Department shall incorporate the SO<sub>2</sub> emissions limits of this Consent Order into the federally enforceable portion of the Operating Permit pursuant to COMAR 26.11.03.20A(1)(d). C.P. Crane LLC further agrees that it shall not object to incorporation of the SO<sub>2</sub> emissions limits of this Consent Order into the Operating Permit.

IN WITNESS WHEREOF, this Consent Order is agreed to and the terms and

conditions herein consented to as evidenced by the parties' respective signatures affixed below as of the day and year written.

# 1. Introduction

## 1.1 Background

The United States Environmental Protection Agency (EPA) promulgated a 1-hour National Ambient Air Quality Standard (NAAQS) for SO<sub>2</sub> in 2010. The 1-hour SO<sub>2</sub> NAAQS has a level set at 75 ppb and the form of the standard is the average of the 99<sup>th</sup> percentile of the daily maximum 1-hour average concentrations realized in each of three consecutive calendar years (the “design value,” or DV).

The EPA is implementing the 2010 1-hour SO<sub>2</sub> NAAQS in an approach that involves either a dispersion modeling or monitoring approach to characterize local SO<sub>2</sub> concentrations near isolated emission sources. EPA’s Data Requirements Rule (DRR) was finalized on August 21, 2015 and H.A. Wagner Generating Station, Brandon Shores Generating Station and C.P. Crane Generating Station were informed that they are subject to the requirements in the DRR.

Talen Energy’s H.A. Wagner Generating Station and Brandon Shores Generating Station and PurENERGY’s C.P. Crane were modeled as part of the Consent Decree Round 2 phase of the SO<sub>2</sub> characterization process. Modeling was relied upon for the characterization, although all SO<sub>2</sub> monitors in the greater Baltimore area show attainment. Modeling provided by Maryland Department of Environment (MDE) supported their recommendation that the area be classified as attainment/unclassifiable made on April 19, 2016. However, on July 1, 2016, based upon use of default modeling approaches, EPA designated portions of Anne Arundel and Baltimore Counties around the H. A. Wagner power plant (Wagner) as non-attainment for the SO<sub>2</sub> primary NAAQS (see Figure 1-1). Per EPA, “a non-attainment area should contain the area violating the NAAQS as well as any adjacent areas (e.g., counties or portions thereof) that contain emissions sources contributing to the violation.”<sup>1</sup> Appendix A of this report contains EPA’s Technical Support Document (TSD)<sup>2</sup> for Maryland Area Designations for the 2010 SO<sub>2</sub> NAAQS. Due to its proximity to Wagner and Brandon Shores Generating Stations, C.P. Crane Generating Station (C.P. Crane) potential-to-emit (PTE) emission rate of 3.5 lb/MMBtu for each unit, EPA included the area around C.P. Crane in the nonattainment designation as well, even including areas with monitored concentrations well below the NAAQS. The locations of the large SO<sub>2</sub> sources in or near the nonattainment area are shown in Figure 1-2.

The MDE is required to prepare and submit a State Implementation Plan (SIP) to EPA that demonstrates the steps taken to achieve attainment of the NAAQS throughout the nonattainment area (NAA). The SIP must include a dispersion modeling study that indicates the expected SO<sub>2</sub> emission reductions required to bring the entire NAA into attainment within 5 years after the effective date of the nonattainment designation (by September 2021). It is desirable in the case of a monitored violation for the attainment demonstration to have controls in place 1 year in advance of the 5-year deadline in order to determine the effect of the controls on the monitor. In this case, there is no monitored violation at all, and the nonattainment area is solely based upon modeling with conservative default assumptions. However, MDE has indicated that SIP emissions inventories are developed based on calendar year. Therefore, it is appropriate for the proposed emission limits associated with modeled NAAQS attainment to be in place by January 1, 2021.

MDE and EPA Region 3 requested that a single modeling protocol and subsequent report for Wagner, Brandon Shores and C.P. Crane be provided for the Anne Arundel and Baltimore Counties non-attainment area. Talen Energy and PurENERGY have both contracted AECOM to submit this modeling report to satisfy the EPA requirements for a 1-hour SO<sub>2</sub> State Implementation Plan (SIP) modeling demonstration for the Baltimore area.

<sup>2</sup> EPA Technical Support Document for Final Designation - Maryland. Available at: [https://www.epa.gov/sites/production/files/2016-06/documents/r3\\_md\\_final\\_designation\\_tsd\\_06302016.pdf](https://www.epa.gov/sites/production/files/2016-06/documents/r3_md_final_designation_tsd_06302016.pdf)

## 1.2 Document Organization

Section 2 provides a review of the ambient background monitor trends. Section 3 provides a discussion of SO<sub>2</sub> emission sources that were included in the modeling demonstration. Section 4 outlines the modeling procedures used, including model options, meteorological data, receptors, and background concentrations. Section 5 provides the results of the modeling for the 1-hour emission rates (EPA refers to these emission rates as “critical emission values”, CEVs) that show modeled NAAQS compliance assuming continuous operation at those rates. EPA’s SIP development guidance for non-attainment areas<sup>3</sup> allows for the consideration of lower longer-term (e.g., up to 30-day) average emission rates that provide for comparable stringency with the 1-hr critical emissions values. Section 6 discusses the approaches used to establish permitted SO<sub>2</sub> emission rates for plant-specific averaging times for the emission sources included in this modeling study.

**Figure 1-2: Locations of Current and Proposed Large SO<sub>2</sub> Sources in the Baltimore Area**

## 2. Review of Ambient Background Monitoring Data

There are two SO<sub>2</sub> monitors located in the Baltimore area, the Essex monitor (#24-005-3001) located northeast of the city and Howard University's Beltsville Laboratory (HU-Beltsville) monitor located southwest of the city. The HU-Beltsville monitor (#24-033-0030) began collecting data in 2006 and the Essex monitor began collecting data in 2003.

Table 2-1 shows the 1-hr SO<sub>2</sub> 99<sup>th</sup> percentiles of the daily 1-hour maximum concentrations from 2007 through 2016 for the Essex and HU-Beltsville SO<sub>2</sub> monitors. The 3-year average design values were above the then-future 1-hour NAAQS in the mid-2000's at the Essex monitor, but regional emissions reductions have reduced ambient monitor concentrations in the last five years and as such, the design values have leveled off to approximately 25% of the 1-hour NAAQS at Essex and 12% of the NAAQS at HU-Beltsville.

**Table 2-1: 99<sup>th</sup> Percentile of the Daily 1-hour Maximum SO<sub>2</sub> Concentrations at the Essex and Beltsville Monitors**

Year	99 <sup>th</sup> Percentile of the Daily 1-hour Maximum Concentrations (ppb)		3-Year Average Design Values (ppb)	
	Essex	Beltsville	Essex	Beltsville
2007	129	34	--	--
2008	56	28	--	--
2009	54	24	79.7	28.7
2010	20	10	43.3	20.7
2011	27	12	33.7	15.3
2012	19	12	22.0	11.3
2013	21	7	22.3	10.3
2014	26	14	22.0	11.0
2015	18	8	21.7	9.7
2016	13	5	19.0	9.0

As shown in Figure 1-2, the Essex monitor is located near or downwind of all sources included in the modeling, and it is inside the nonattainment area (although the monitored concentrations are less than half of the NAAQS). Figure 2-1 shows a pollution rose for combined years 2012-2014. The wind direction data is taken from Baltimore-Washington International Airport, MD ASOS station. The predominant winds for the highest (dark red) concentrations are from the south/southwest (Fort Smallwood and Wheelabrator) and east/northeast (from C.P. Crane). As such, to avoid double-counting the SO<sub>2</sub> concentrations from the modeled sources with the regional background estimates, Talen Energy and PurENERGY used the HU-Beltsville monitor when developing the ambient background concentrations to be included in this modeling analysis. The development of the background concentrations input to AERMOD is discussed in Section 4.7.

**Figure 2-1: Pollution Rose for Essex SO<sub>2</sub> Monitor for years 2014-2016**

## 3. Emission Source Inventory

### 3.1 Sources Modeled

The EPA Technical Support Document (TSD; see Appendix A) discusses SO<sub>2</sub> emission sources that were recommended by EPA to be included in the Maryland SIP modeling analysis.

Figure 1-1 shows the sources located within and near the Anne Arundel and Baltimore Counties, MD NAA. The sources include two boilers at C.P. Crane and Brandon Shores, four boilers at H.A. Wagner and an incinerator at Wheelabrator. Table 3-1 lists the stack parameters for the sources that were modeled for full-load operations. Varying load stack parameters for Brandon Shores and Wagner Unit 3 are discussed in Sections 6.3 and 6.5.2, respectively.

For purposes of modeling a new source for permitting, emission rates and stack parameters for the 1-hour SO<sub>2</sub> SIP modeling typically are held constant using full load conditions. However, the SO<sub>2</sub> Nonattainment Modeling Guidance<sup>3</sup> allows for some flexibility for sources that do not operate during all hours of the year or which have infrequent higher emission rates using the methodologies for rolling 30-day emission rates in Appendices B, C and D of the guidance. As such, longer-term permitted emission rates for the units at Brandon Shores and Wagner have been calculated in accordance with EPA's Nonattainment Modeling Guidance, using modeling procedures described in EPA's Appendix B and are provided in Section 6 of this report. C.P. Crane will commit to a 1-hour emission rate of 2,900 lb/hr (365.3939 g/s) as a cap for Units 1 and 2 combined. The 1-hour SO<sub>2</sub> emission rate for the incinerator at Wheelabrator included as a background source in the modeling was 375 lb/hr (47.25 g/s), which was provided by MDE. Based on EPA's National Emission Inventory (NEI) database and the inventory included in the SO<sub>2</sub> DRR, no other large stationary SO<sub>2</sub> sources (i.e., > 100 TPY) exist within 20 kilometers of the Fort Smallwood Complex.

#### 3.1.1 Brandon Shores Units

Brandon Shores Units 1 and 2 exhaust to two flues in one shell with height and internal exit diameter values as reported in Table 3-1. For the modeling demonstration, a single merged stack is used for Units 1 and 2. To account for this merged stack in the modeling, the average velocity, weighted average temperature, and equivalent stack diameter were used in AERMOD, consistent with EPA Model Clearinghouse Memo 91-II-01.

Brandon Shores Units 1 and 2 are solid fossil fuel fired generating units with low-sulfur (< 0.3% S) No. 2 oil used for burner start-up purposes. A description of a typical startup sequence for these units is provided below.

For startup, low-sulfur No. 2 oil ignitors are used in the boiler for approximately 16 hours, at which point the main (coal-fired) burners begin to be turned on. More coal burners are transitioned into service over the next ~10 hours, at which point the turbine/generator becomes parallel with the grid. Minimum stable electric load is then typically achieved within the next 6 hours. All flue gases pass through the scrubber, which is operational at all times; there is no bypass.

#### 3.1.2 H.A. Wagner Units

H.A. Wagner Unit 1 is a No. 6 oil or natural gas fired unit. Unit 3 is a coal fired unit with natural gas used for start-up. Unit 4 is a No. 6 oil fired unit with natural gas fired used for start-up. Wagner Unit 2 will cease burning coal and will have zero or insignificant (less than 0.1 g/s) SO<sub>2</sub> emissions by the end of June 2020 due to NO<sub>x</sub> RACT and therefore is not included as an SO<sub>2</sub> source for the modeling demonstration. Talen Energy will commit to via a consent agreement to cease burning coal or fuel oil in Wagner Unit 2. The following are descriptions of the typical startup sequences for these units.

Wagner Unit 1: natural gas ignitors are used in the boiler for approximately 8 hours, at which point main burners (gas or oil) are turned on and the turbine/generator becomes parallel with the grid. Minimum stable electric load is then typically achieved within the next hour.

Wagner Unit 3: natural gas ignitors are used in the boiler for approximately 6 hours, at which point main burners (coal-fired) begin to be turned on. More coal burners are transitioned into service over the next ~12 hours, at which point the turbine/generator becomes parallel with the grid. Minimum stable electric load is then typically achieved within the next four hours. Dry sorbent injection is commenced for SO<sub>2</sub> and acid gas control prior to achieving minimum load.

Wagner Unit 4: natural gas ignitors are used in the boiler for approximately 10 hours, at which point the main burners (oil) are turned on. More oil burners are transitioned into service over the next ~8 - 10 hours, at which point, the turbine/generator becomes parallel with the grid. Minimum stable electric load is then typically achieved within the next two hours.

Future operational changes to be in place by January 2021 at Wagner that will result in lower SO<sub>2</sub> emissions include;

- Unit 1 will operate no more than 5% of the hours during any calendar year (438 hours), and will fire low-sulfur (0.3%) No. 6 oil (no limit on hours operated using natural gas);
- Unit 3 will burn lower-sulfur coal, such as New Source Performance Standard (NSPS) compliant coal (1.1 lb SO<sub>2</sub>/MMBtu);
- Use of a specialized sorbent in the dry sorbent injection system is expected to reduce SO<sub>2</sub> emissions 30% (on a rolling 30-day basis) for Wagner Unit 3; and
- Unit 4 will operate no more than 5% of the hours in any calendar year (438 hours), and will fire low-sulfur (0.3%) No. 6 oil.

### 3.1.3 C.P. Crane Units

C.P. Crane controls SO<sub>2</sub> emissions by means of burning lower sulfur coal than is currently permitted in tandem with a dry sorbent injection (DSI) system. For Crane, DSI has been known to decrease SO<sub>2</sub> by ~5-10%, depending on the quantity injected.

C.P. Crane's Unit 1 had between 12 and 19 startup and shut down events per year during the 2014 to 2016 period. Startup operations lasted between 9 and 36 hours for Unit 1. During the first half of startup, the fuel type is a co-firing natural gas and coal, with the second half of startup using only coal. During the same 3-year period (2014-2016), C.P. Crane's Unit 2 had between 21 and 29 start up and shut down events per year. Unit 2 startups lasted between 5 and 24 hours, with natural gas firing only for the first half of startup and coal only for the second half of the startup period.

### 3.1.4 Intermittent Sources

Intermittent sources and transient conditions such as emergency generators and auxiliary boilers were not modeled as explained in the March 2011 EPA guidance document<sup>4</sup> for modeling 1-hour NO<sub>2</sub> and SO<sub>2</sub>. These emission sources are of insufficient duration and frequency to affect NAAQS compliance as shown in Table 3-2.

---

**Table 3-2 Hours of Operation for Auxiliary Sources**

Facility	Source Description	2016 Operating Hours	2016 SO <sub>2</sub> Emissions (tons)
Brandon Shores	#1 Auxiliary Boiler: Zurn (Model 18M Keystone) No. 2 oil fired boiler	6	0.0601
	#2 Auxiliary Boiler: Zurn (Model 18M Keystone) No. 2 oil fired boiler	0	0.0000
	2 Quench Pumps (500 HP diesel-fired internal combustion engine) that supply water to the flue gas desulfurization (FGD) system in emergencies	29.5	0.0010
	Emergency generator (670 HP diesel-fired internal combustion engine) to provide back-up power	5.7	0.0003
H.A. Wagner	Combustion turbine (No. 2 oil fired) used to supply “black start” capability to H.A. Wagner and for peaking operation	44.7	0.3700
Crane	#2 Auxiliary Boiler fired by No. 2 oil (ULSD) used for supplying steam rated at 25 MMBtu/hour	7	0.0280
	#3 Auxiliary Boiler fired by natural gas with No. 2 fuel (ULSD) as a back-up and used for supplying steam rated at 62.5 MMBtu/hour	0 hours Oil, 4,248 hours Gas	0.0800
	Combustion turbine rated at 14 MW (summer capability) fired by No. 2 oil (ULSD)	55	0.011
	600 HP Emergency Generator (ULSD)	7	3E-05

## 4. Modeling Procedures

### 4.1 Dispersion Model Selection

This modeling analysis utilized the current EPA-recommended version of the AERMOD dispersion model (Version 16216r) to evaluate air quality impacts from the emission sources of interest. The AERMOD modeling system consists of two preprocessors and the dispersion model. AERMET is the meteorological preprocessor component and AERMAP is the terrain pre-processor component that characterizes the terrain and generates receptor elevations along with critical hill heights for those receptors. Table 4-1 summarizes the versions of AERMOD and its preprocessors.

**Table 4-1 Versions of AERMOD and Its Preprocessors Used in Modeling Demonstration**

Dispersion Model and Preprocessors	Version No.
AERMOD	16216r
AERMET	16216
AERMINUTE	15272
AERSURFACE	13016
BPIP-PRIME	04274
AERMAP	11103

### 4.2 Land Use Classification

One of the factors affecting input parameters to dispersion models is the presence of either rural or urban conditions near the source site and the meteorological site(s). The choice of rural or urban for dispersion conditions at the source site depends upon the land use characteristics within 3 kilometers of the facility being modeled (Appendix W to 40 CFR Part 51)<sup>5</sup>. Factors that affect the rural/urban choice, and thus the dispersion, include the extent of vegetated surface area, the water surface area, types of industry and commerce, and building types and heights within this area.

#### 4.2.1 Land Use Analysis for the Fort Smallwood Complex

An objective analysis using the Auer Method was conducted using ArcGIS to extract the land use categories within a 3-km radius centered on the Fort Smallwood Complex using the digitized 2011 NLCD data. Figure 4-1 shows the land categories within 3 km of the Fort Smallwood Complex. EPA mentions in their comment that for sites that have over 50% of the land use categorized as water, this could skew the analysis and lead to an improper “rural” designation. Table 4-2 shows that 39.7% of the land use within the 3-km radius consists of open water, which is below the 50% threshold. The land types defined as rural under the Auer Land Use Method is approximately 85%.

In addition, the land use surrounding the Fort Smallwood Complex was examined while ignoring the areas classified as water. This secondary analysis yields approximately 75% of the land cover as rural, still well above the 50% criteria threshold (shown in Table 4-3).

For these reasons and because MDE has historically modeled the Fort Smallwood Complex as rural, we conclude that the designation of rural is appropriate for the modeling of the Fort Smallwood Complex for this application.

<sup>5</sup> EPA’s Guideline on Air Quality Models, available at [https://www3.epa.gov/ttn/scram/appendix\\_w/2016/AppendixW\\_2017.pdf](https://www3.epa.gov/ttn/scram/appendix_w/2016/AppendixW_2017.pdf).

## 4.2.2 Land Use Analysis for C.P. Crane

An objective analysis using the Auer Method was conducted using ArcGIS to extract the land use categories within a 3-km radius centered on C.P. Crane using the digitized 2011 NLCD data. Figure 4-2 shows the land categories within 3 km of C.P. Crane. As in the case for Fort Smallwood, EPA mentions in their comment that for sites that have over 50% of the land use categorized as water, this could skew the analysis and lead to an improper “rural” designation. Table 4-4 shows that 45.5% of the land use within the 3 km radius consists of open water, which is below the 50% threshold. The land types defined as rural under the Auer Land Use Method is approximately 97%.

In addition, the land use surrounding C.P. Crane was examined while ignoring the areas classified as water. This secondary analysis yields approximately 95% of the land cover as rural, still well above the 50% criteria threshold (shown in Table 4-5).

For these reasons and because MDE has previously modeled C.P. Crane as rural, we conclude that the designation of rural is appropriate for the modeling of the C.P. Crane for this application.

**Table 4-4: Land Use Analysis with 2011 NLCD for C.P. Crane**

Crane Study Area Auer's Analysis				Crane 3km Ring		
NLCD Value	NLCD 2011 Description	Auer's Code	Auer's Class	Cell Count	Percentage	Totals
23	Developed, Medium Intensity	R2/R3	Urban	789	2.50%	2.94%
24	Developed, High Intensity	I1/I2/C1		139	0.44%	
11	Open Water	A5	Rural	14,328	45.46%	97.06%
21	Developed, Open Space	A1/R4		2,618	8.31%	
22	Developed, Low Intensity	R1		1,943	6.17%	
31	Barren Land (Rock/Sand/Clay)	A3		15	0.05%	
41	Deciduous Forest	A4		2,073	6.58%

## 4.3 Good Engineering Practice (GEP) Analysis

Federal stack height regulations limit the stack height used in performing dispersion modeling to predict the air quality impact of a source for purposes of setting a new emission limit for stacks placed into operation after 1970. Sources must be modeled at the actual physical stack height unless that height exceeds the Good Engineering Practice (GEP) formula stack height. If the physical stack height is less than the formula GEP height, the potential for the source's plume to be affected by aerodynamic wakes created by the building(s) must be evaluated in the dispersion modeling analysis.

A GEP formula stack height analysis has been performed for sources of interest located at the Brandon Shores, Wagner, C.P. Crane Generating Stations, and Wheelabrator in accordance with the EPA's "Guideline for Determination of Good Engineering Practice Stack Height" (EPA, 1985)<sup>6</sup>. A GEP stack height is defined as the greater of 65 meters (213 feet), measured from the ground elevation of the stack, or the formula height ( $H_g$ ), as determined from the following equation:

$$H_g = H_B + 1.5 L$$

where

$H_B$  is the height of the nearby structure which maximizes  $H_g$ , and

$L$  is the lesser dimension (height or projected width) of the building ( $H_B$ ).

For a squat structure, i.e., height less than projected width, the formula reduces to:

$$H_g = 2.5H_B$$

In the absence of influencing structures, a "default" GEP stack height is credited up to 65 meters (213 feet). Both the height and the width of the building are determined through a vertical cross-section perpendicular to the wind direction. In all instances, the GEP formula height is based upon the highest value of  $H_g$  as determined from  $H$  and  $L$  over all nearby buildings over the entire range of possible wind directions. For the purposes of determining the GEP formula height, only buildings within  $5L$  of the source of interest are considered. The stacks to be included in the modeling demonstration and their commission dates are presented in Table 4-6.

**Table 4-6: Stack Commission Dates**

Facility	Stack	Commission Date
<b>C.P. Crane</b>	Unit 1	July 1961
	Unit 2	February 1963
<b>Brandon Shores</b>	Dual-flue FGD Units 1 & 2	2010
<b>H.A. Wagner</b>	Unit 1	February 1956
	Unit 2	January 1959
	Unit 3	August 1966
	Unit 4	August 1972
<b>Wheelabrator</b>	Incinerator	1985

The GEP analyses were conducted with the latest version of the US EPA's Building Profile Input Program software (BPIP-PRIME version 04274). The locations and dimensions of the buildings/structures relative to the exhaust stacks for Brandon Shores, Wagner, C.P. Crane Generating Stations, and Wheelabrator are depicted in Figures 4-3 through 4-6. Building heights and the base elevations of buildings and stacks

<sup>6</sup> Available at <http://www.epa.gov/scram001/guidance/guide/gep.pdf>.

were updated from previous modeling based on 2004 and 2014 USGS LIDAR data<sup>7</sup> and confirmed with Google Earth Pro (shown in Figures 4-7 and 4-9) for the Fort Smallwood Complex and Wheelabrator. 3D representations of the buildings and stacks as output from BPIP-PRIME are shown in Figures 4-10 and 4-12. Historical LIDAR data are not available for the area near C.P. Crane, likely due to its proximity to Aberdeen Proving Ground.

## 4.4 Meteorological Data Processing

The meteorological data required for input to AERMOD was created with the latest version of AERMET (16216) using the adjusted u\* option. This option is now a default option per the recently promulgated Appendix W. Hourly surface observations from Baltimore-Washington International Airport, MD along with concurrent upper air data from Sterling, VA was used as input to AERMET with both 1-minute and 5-minute wind speed and direction data incorporated in AERMET Stage 2. The surface data (wind direction, wind speed, temperature, sky cover, and relative humidity) is measured 10 m above ground level<sup>8</sup>. The location of the anemometer in decimal degrees is 39.1733°N 76.6841°W. A wind rose for 2012-2016 is shown in Figure 4-13.

AERMET creates two output files for input to AERMOD:

- **SURFACE:** a file with boundary layer parameters such as sensible heat flux, surface friction velocity, convective velocity scale, vertical potential temperature gradient in the 500-meter layer above the planetary boundary layer, and convective and mechanical mixing heights. Also provided are values of Monin-Obukhov length, surface roughness, albedo, Bowen ratio, wind speed, wind direction, temperature, and heights at which measurements were taken.
- **PROFILE:** a file containing multi-level meteorological data with wind speed, wind direction, temperature, sigma-theta ( $\sigma_\theta$ ) and sigma-w ( $\sigma_w$ ) when such data are available. For this application involving representative data from the nearest NWS station, the profile file contained a single level of wind data and the temperature data.

AERMET requires specification of site characteristics including surface roughness ( $z_o$ ), albedo ( $r$ ), and Bowen ratio ( $B_o$ ). These parameters were developed according to the guidance provided by US EPA in the recently revised AERMOD Implementation Guide<sup>9</sup> (AIG).

The AIG provides the following recommendations for determining the site characteristics:

1. The determination of the surface roughness length should be based on an inverse distance weighted geometric mean for a default upwind distance of 1 kilometer relative to the measurement site. Surface roughness length may be varied by sector to account for variations in land cover near the measurement site; however, the sector widths should be no smaller than 30 degrees.
2. The determination of the Bowen ratio should be based on a simple un-weighted geometric mean (i.e., no direction or distance dependency) for a representative domain, with a default domain defined by a 10-km by 10-km region centered on the measurement site.
3. The determination of the albedo should be based on a simple un-weighted arithmetic mean (i.e., no direction or distance dependency) for the same representative domain as defined for Bowen ratio, with a default domain defined by a 10-km by 10-km region centered on the measurement site.

The AIG recommends that the surface characteristics be determined based on digitized land cover data. EPA has developed a tool called AERSURFACE that can be used to determine the site characteristics

<sup>7</sup> <http://earthexplorer.usgs.gov/> under Digital Elevation/LIDAR.

<sup>8</sup> Anemometer height obtained from National Weather Service ASOS Implementation site. <http://www.nws.noaa.gov/ops2/Surface/asosimplementation.htm>

<sup>9</sup> Available at [https://www3.epa.gov/ttn/scram/7thconf/aermod/aermod\\_implmnt\\_guide\\_3August2015.pdf](https://www3.epa.gov/ttn/scram/7thconf/aermod/aermod_implmnt_guide_3August2015.pdf).

based on digitized land cover data in accordance with the recommendations from the AIG discussed above. AERSURFACE<sup>10</sup> incorporates look-up tables of representative surface characteristic values by land cover category and seasonal category. AERSURFACE was applied with the instructions provided in the AERSURFACE User's Guide.

At the direction of the reviewing agencies, a sensitivity analysis was conducted to determine the representativeness of the BWI airport surface characteristics to those at C.P. Crane and Fort Smallwood. To determine the representativeness of the BWI airport site for surface characteristics in comparison to the area surrounding Fort Smallwood, AERSURFACE was applied for a single 1-km sector around three sites (C.P. Crane, Fort Smallwood and BWI airport) using average moisture conditions. The results of the three AERSURFACE runs are presented in Table 4-7. Table 4-7 shows that the albedo values are very similar between the three sites. There is some variation in the Bowen ratios and surface roughness at the different sites. The surface roughness values are all relatively low (less than 0.16 meters), with BWI having a surface roughness value between C.P. Crane and Fort Smallwood.

Based on results of the sensitivity analysis, the modeling used monthly surface roughness and albedo from the BWI airport, with the Bowen ratio from Fort Smallwood. The annual values for comparison between the three sites are highlighted blue in Table 4-7.

**Table 4-7: AERSURFACE Land Use Comparison**

Site	Annual Average Land Use		
	Albedo	Bowen Ratio	Z <sub>0</sub> (m)
BWI Airport	0.16	0.76	0.051
C.P. Crane	0.13	0.22	0.024
Fort Smallwood	0.13	0.33	0.157

The current version of AERSURFACE (Version 13016) supports the use of land cover data from the USGS National Land Cover Data 1992 archives<sup>11</sup> (NLCD92). The NLCD92 archive provides data at a spatial resolution of 30 meters based upon a 21-category classification scheme applied over the continental U.S. The AIG recommends that the surface characteristics be determined based on the land use surrounding the site where the surface meteorological data were collected.

As recommended in the AIG for surface roughness, the 1-km radius circular area centered at the meteorological station site can be divided into sectors for the analysis; the default 12 sectors will be used for this analysis.

In AERSURFACE, the various land cover categories are linked to a set of seasonal surface characteristics. As such, AERSURFACE requires specification of the seasonal category for each month of the year. The following five seasonal categories are supported by AERSURFACE, with the applicable months of the year specified for this site.

1. Midsummer with lush vegetation (June-August).
2. Autumn with un-harvested cropland (September- November).
3. Late autumn after frost and harvest, or winter with no snow (December - February)
4. Winter with continuous snow on ground (none).
5. Transitional spring with partial green coverage or short annuals (March - May).

<sup>10</sup> Documentation available at [http://www.epa.gov/ttn/scram/dispersion\\_related.htm#aersurface](http://www.epa.gov/ttn/scram/dispersion_related.htm#aersurface).

<sup>11</sup> See additional information at <http://landcover.usgs.gov/natl/landcover.php>.

AECOM reviewed snow cover data<sup>12</sup> for BWI during the 2012-2016 period to determine if any winter month had snow cover for more than half of the days in the month. BWI reported only eight (non-consecutive) days with snow cover in January 2014 (26% of the month), and seven (consecutive) days in February 2014 (25% of the month). During 2015, however, February had 14 days with snow cover, qualifying this month to be characterized as “winter with continuous snow on ground”. Therefore, a separate AERSURFACE run was conducted to account for this month for snow cover in 2015. The two runs were then concatenated together to represent each month’s characterization correctly.

For Bowen ratio, the land use values are linked to three categories of surface moisture corresponding to average, wet, and dry conditions. The surface moisture condition for the site may vary depending on the meteorological data period for which the surface characteristics will be applied. AERSURFACE applies the surface moisture condition for the entire data period. Therefore, if the surface moisture condition varies significantly across the data period, then AERSURFACE can be applied multiple times to account for those variations.

As such, the surface moisture condition for each season was determined by comparing precipitation for the period of data to be processed to the 30-year climatological record, selecting “wet” conditions if precipitation is in the upper 30<sup>th</sup>-percentile, “dry” conditions if precipitation is in the lower 30<sup>th</sup>-percentile, and “average” conditions if precipitation is in the middle 40<sup>th</sup>-percentile. The 30-year precipitation data set used in this modeling was taken from the National Climatic Data Center<sup>13</sup>.

The monthly designations of surface moisture that were input to AERSURFACE are summarized in Table 4-8.

**Table 4-8: AERSURFACE Bowen Ratio Condition Designations**

Month	Bowen Ratio Category				
	2012	2013	2014	2015	2016
January	Dry	Average	Average	Wet	Average
February	Average	Dry	Wet	Average	Wet
March	Dry	Average	Average	Average	Dry
April	Dry	Dry	Wet	Wet	Dry
May	Dry	Average	Average	Dry	Wet
June	Average	Wet	Average	Wet	Average
July	Average	Dry	Average	Average	Wet
August	Wet	Dry	Wet	Dry	Average
September	Dry	Dry	Average	Average	Average
October	Wet	Wet	Average	Average	Dry
November	Dry	Average	Average	Average	Dry
December	Average	Wet	Average	Wet	Average

## 4.5 Model Receptor Grid and Terrain

Receptors are placed in nested Cartesian grids centered on the Fort Smallwood Complex and C.P. Crane with the following spacing:

<sup>12</sup> <http://www.ncdc.noaa.gov/snow-and-ice/daily-snow/>

<sup>13</sup> <http://www.ncdc.noaa.gov/cdo-web/>

- Every 25 meters along the ambient boundary,
- Every 100 meters out to a distance of 15 km, and
- Every 500 meters between 15 and 25 km.

The receptor grid used in the modeling is consistent to what was described in the approved modeling protocol. The current version of AERMAP has the ability to process USGS National Elevation Dataset (NED) data in place of Digital Elevation Model files. The appropriate file for 1-arc-second, or 30-m, NED data was obtained from the Multi-Resolution Land Characteristics Consortium (MRLC) link at <https://viewer.nationalmap.gov/viewer/>. AERMAP assigns elevation heights and critical hill heights to each receptor based on the terrain dataset. The receptor grid is shown in Figures 4-14, 4-15 and 4-16.

Receptors were not placed on Talen Energy property that is not accessible to the public. Public access is restricted along the property boundary for the H.A. Wagner and Brandon Shores Power Plants by: 1) a physical fence (including gates) as denoted by the yellow lines in Figure 4-17 and 2) no trespassing signs along the orange lines in Figure 4-17 that extends the immediate waters alongside the fuel unloading pier.

Receptors were not placed on C.P. Crane property that is not accessible to the public. Public access is restricted along the property boundary for the C.P. Crane Generating Station by: 1) a physical fence (including gates) as denoted by the yellow lines in Figure 4-18 and 2) a retaining wall prevents public vessels from entering the nearby waters of C.P. Crane as denoted by the light green line in Figure 4-18. A close-up photo taken just offshore shows the retaining wall from a different angle in Figure 4-19.

With multiple sources included as part of the proposed modeling demonstration, a supplemental analysis was performed to ensure there are no NAAQS violations occurring within the ambient air boundary at Fort Smallwood Complex from C.P. Crane sources and within C.P. Crane's ambient air boundary from sources at the Fort Smallwood Complex. To accomplish this, receptors were placed on C.P. Crane's property and all modeled sources (excluding C.P. Crane stacks) were modeled at these receptors to ensure there is not a NAAQS violation. Additionally, receptors were placed on Fort Smallwood's property and all modeled sources (excluding Brandon Shores and H.A. Wagner stacks) were at these receptors to ensure there is not a NAAQS violation. The modeling files that support this demonstration are included in the model archive.

## 4.6 Model Configurations and Options

AERMET (version 16216) and AERMOD (version 16216r) was run with the updated "ADJ\_U\*" option in AERMET and the DEFAULT option in AERMOD to use the ADJ\_U\* meteorological data. Appendix W states, "EPA is adopting the proposed ADJ\_U\* option in AERMET as a regulatory option for the use in AERMOD for sources using standard NWS airport meteorological data, site-specific meteorological data without turbulence parameters, or prognostic meteorological inputs derived from prognostic meteorological models." For this modeling demonstration, standard NWS airport meteorological data from the Baltimore-Washington International (BWI) Airport and the ADJ\_U\* option is appropriate.

## 4.7 Background Concentrations

The HU-Beltsville, MD monitor (Site #24-033-0030), which is located about 33 km to the southwest of the Fort Smallwood Complex and 52 km southwest of C.P. Crane, in Prince Georges County, was used to determine the uniform regional background component for the NAAQS SO<sub>2</sub> modeling. EPA's March 2011 clarification memo<sup>14</sup> regarding 1-hour SO<sub>2</sub> NAAQS modeling allows for an approach using the 99<sup>th</sup> percentile monitored values whereby the background values vary by season and by hour of the day. AECOM applied this approach to its modeling, using data from the 3-year period of 2014 – 2016 to be added to the three years of modeled concentrations. The SO<sub>2</sub> concentrations that were used are listed in Table 4-9. Figure 4-20 shows a plot of the hourly background values by season and hour.

<sup>14</sup> Available at [http://www.epa.gov/ttn/scram/guidance/clarification/Additional\\_Clarifications\\_AppendixW\\_Hourly-NO2-NAAQS\\_FINAL\\_03-01-2011.pdf](http://www.epa.gov/ttn/scram/guidance/clarification/Additional_Clarifications_AppendixW_Hourly-NO2-NAAQS_FINAL_03-01-2011.pdf).

According to the EPA's "Table 5c Monitoring Site Listing for Sulfur Dioxide 1-Hour NAAQS" ([https://www.epa.gov/sites/production/files/2016-07/so2\\_designvalues\\_20132015\\_final\\_07\\_29\\_16.xlsx](https://www.epa.gov/sites/production/files/2016-07/so2_designvalues_20132015_final_07_29_16.xlsx)), the 75% data completeness criteria for 2014 through 2016 (Column W) is satisfied with all years above 94%, therefore, the HU-Beltsville 1-hour SO<sub>2</sub> monitoring data is sufficiently complete and is acceptable to use in the modeling.

One direction sector that is unique to the Fort Smallwood site involves winds generally from the east (upwind sector from 70 to 130 degrees), for which the upwind fetch involves approximately 20 kilometers over open water, and then at least 10 additional km further to the east with no large SO<sub>2</sub> sources on the eastern shore of the Chesapeake Bay before reaching Fort Smallwood. For this sector only, AECOM included a sector-dependent background concentration, as described in EPA's September 2014 Clarification Memo<sup>15</sup>. The AERMOD User's Guide Addendum<sup>16</sup> states that such sectors should be 60 degrees or more (a warning will be issued for sectors less than 60 degrees).

AECOM reviewed SO<sub>2</sub> monitoring data at the Horn Point ambient monitor in Dorchester County for when wind directions at the Horn Point anemometer are between 70° and 130° (a visual of this sector is shown in Figure 4-21). A 3-year (2014-2016) 99<sup>th</sup> percentile design value from Horn Point was used in place of the HU-Beltsville monitoring data for this defined sector. The Horn Point design 3-year design value during this period was calculated using only hours when winds at this monitor were between 70° and 130°. This yielded a preliminary design value of 2.5 ppb. The 2014 design value is 4.7 ppb, the 2015 design value is 2 ppb, and the 2016 design value is 1 ppb, showing a downward trend over the three year period. The 2017 hourly SO<sub>2</sub> data through September shows similar values to 2016, with a design value over all hours and wind directions to be 1 ppb. AECOM used the value (2.5 ppb) for the overwater sector, with the Beltsville monitor hour-of-day/seasonal values used for all other directions. Figure 4-20 shows the 2.5 ppb (6.55 µg/m<sup>3</sup>) from Horn Point plotted against the season hour-of-day 3-year average value for HU-Beltsville.

The 2014-2016 ambient SO<sub>2</sub> background measurement data were obtained from EPA's Air Quality System Data Mart (AQSDM)<sup>17</sup>.

The final background input file read by AERMOD was specified as hourly values. Most of the hourly values used the 3-year averaged seasonal numbers from HU-Beltsville. For hours when the wind from BWI was between 70° and 130°, the 3-year design value (2.5 ppb) from Horn Point as discussed above was used.

## 5. SO<sub>2</sub> NAAQS Attainment Modeling Results and Determination of Critical Emission Values

The critical emission value (CEV) for a facility is the maximum 1-hour average emission rate that, when combined with background, results in a design concentration that does not exceed the NAAQS. Initial modeling using emission rates reflecting either the current 1-hour emission limits (Wheelabrator), future 1-hour emission limits (C.P. Crane), or the highest 1-hour average emission rate during future (post-reduction in 2021) normal operations (H.A. Wagner and Brandon Shores) was performed for this modeling effort. Since Wagner Units 1 and 4 operate less than 5% of the time (and could be considered infrequent sources), their “critical emission value” is zero (not operating mode). This modeling followed the procedures noted in Section 4, and the cumulative source impacts at each model receptor were summed with regional background.

This is not to say that Wagner 1 and 4 emissions are neglected in the analysis, nor that they are not allowed to operate. Section 6 will describe how, using EPA Guidance Appendix B procedures, these infrequent emitters have been modeled with their frequency of operation factored in along with Brandon Shores and Wagner 3 with conservatively high emission rates in 1,000 different modeling years and the results demonstrate attainment of the SO<sub>2</sub> NAAQS.

The CEV analysis was conducted for two emission cases involving sources in the Fort Smallwood Complex because of the different operating scenarios for the multiple sources that could occur:

- Case 1: Brandon Shores Units 1 & 2 and Wagner Unit 3 are assumed to be continuously operating, with Wagner Units 1 and 4 not operating.
- Case 2: Brandon Shores Units 1 & 2 are assumed to be operating continuously at the same emission rate as the total emissions from Case 1 for Brandon Shores 1 and 2 as well as Wagner 3, with all Wagner Units not operating.

Both cases, with the same hourly emission rate total in each case, passed with modeled concentrations (including ambient background) below the NAAQS. Our modeling determined that the modeling concentration results normalized by emissions are lower for Brandon Shores operating alone (due to reduced downwash effects and merged flues) than for the combination of Brandon Shores and Wagner Unit 3. Therefore, a combined CEV emission rate (Brandon Shores Units 1 and 2 plus Wagner Unit 3) for the first emission case of both plants operating was found to be applicable to the second case as well, with some margin under the NAAQS for the second case with the same combined emission rate.

Results showed attainment with the 1-hour SO<sub>2</sub> NAAQS throughout the NAA for both emission cases described above. Additional details of the critical emission value modeling results are provided in the following sub-sections.

### 5.1 Model Results with Continuous Operation of Brandon Shores and Wagner Unit 3 (Case 1)

The emission rates used in the 1-hour critical emission rate model runs are presented in Table 5-1 for Brandon Shores and Wagner Unit 3 emission case.

Figure 5-1 shows the 1-hour SO<sub>2</sub> isopleths for this compliance run with the peak impact (including background) of 196.40 µg/m<sup>3</sup> located approximately 4 km west-northwest of the Fort Smallwood Complex. Figures 5-2 and 5-3 show the isopleths and peak impact around Fort Smallwood Complex and Crane. A secondary maximum impact of 194.82 µg/m<sup>3</sup> is located about 1.5 km west of Crane, as shown in Figure 5-3.

Tables 5-2 and 5-3 present the source culpability at the peak receptor near each plant for the controlling concentrations. The total concentration at the receptor is presented in the first row, while the remaining rows present the source contributions as concentrations in µg/m<sup>3</sup> and also as percentages of the total.

The non-attainment guidance issued by EPA in April 2014<sup>18</sup> allows for the consideration of longer emission averaging times that provide for comparable stringency with the critical emission values that can still be protective of the NAAQS. This analysis approach is discussed further in Section 6.

**Table 5-1: Emission Rates Used for Critical Value SO<sub>2</sub> NAAQS Compliance Modeling with Continuous Operation of Brandon Shores and Wagner Unit 3 (Case 1)**

<b>Source</b>	<b>Critical Emission Value - SO<sub>2</sub> Emission Rates Modeled in Compliance Run (lb/hr)</b>	<b>Critical Emission Value - SO<sub>2</sub> Emission Rates Modeled in Compliance Run (g/s)</b>
Crane Unit 1 & 2	2,900	365.4
Brandon Shores Merged Stack	2,851	359.2
Wagner Unit 1	0	0.0
Wagner Unit 3	2,299	289.7
Wagner Unit 4	0	0.0
Wheelabrator	375	47.3

Note: Total emissions from Brandon Shores and Wagner 3 is: 5,150 lb/hr.

<sup>18</sup> <http://www3.epa.gov/airquality/sulfurdioxide/pdfs/20140423guidance.pdf>

**Table 5-2: Source Contributions for Peak Impact near Fort Smallwood Complex for Continuous Operation of Brandon Shores and Wagner Unit 3 (Case 1)**

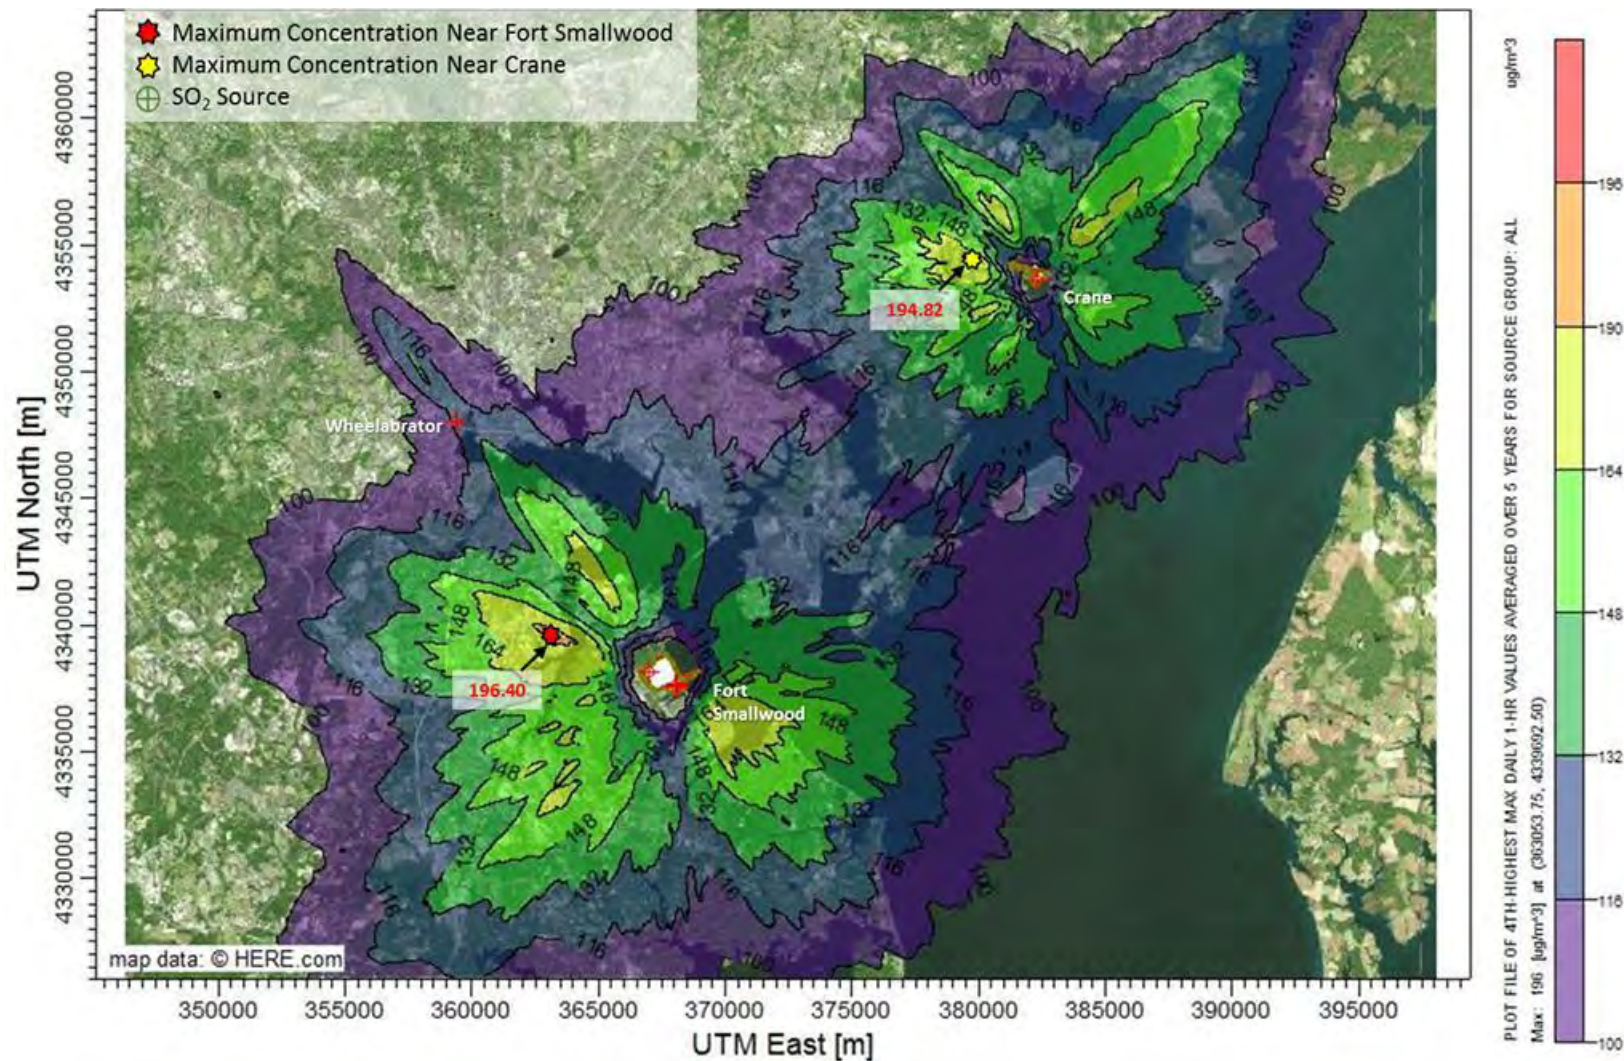

<b>Source</b>	<b>Concentration (<math>\mu\text{g}/\text{m}^3</math>)</b>	<b>Percent Contribution</b>
Crane Unit 1 & 2	0.61	0.3%
Brandon Shores Merged Stack	85.64	43.6%
Wagner Unit 1	0.00	0.0%
Wagner Unit 3	102.70	52.3%
Wagner Unit 4	0.00	0.0%
Wheelabrator	0.17	0.1%
Ambient Background	7.28	3.7%
Peak Impact (Total)	196.40	100%

**Table 5-3: Source Contributions for Peak Impact near Crane for Continuous Operation of Brandon Shores and Wagner Unit 3 (Case 1)**

<b>Source</b>	<b>Concentration (<math>\mu\text{g}/\text{m}^3</math>)</b>	<b>Percent Contribution</b>
Crane Unit 1 & 2	185.94	95.5%
Brandon Shores Merged Stack	0.67	0.3%
Wagner Unit 1	0.00	0.0%
Wagner Unit 3	0.66	0.3%
Wagner Unit 4	0.00	0.0%
Wheelabrator	0.14	0.1%
Ambient Background	7.41	3.8%
Peak Impact (Total)	194.82	N/A

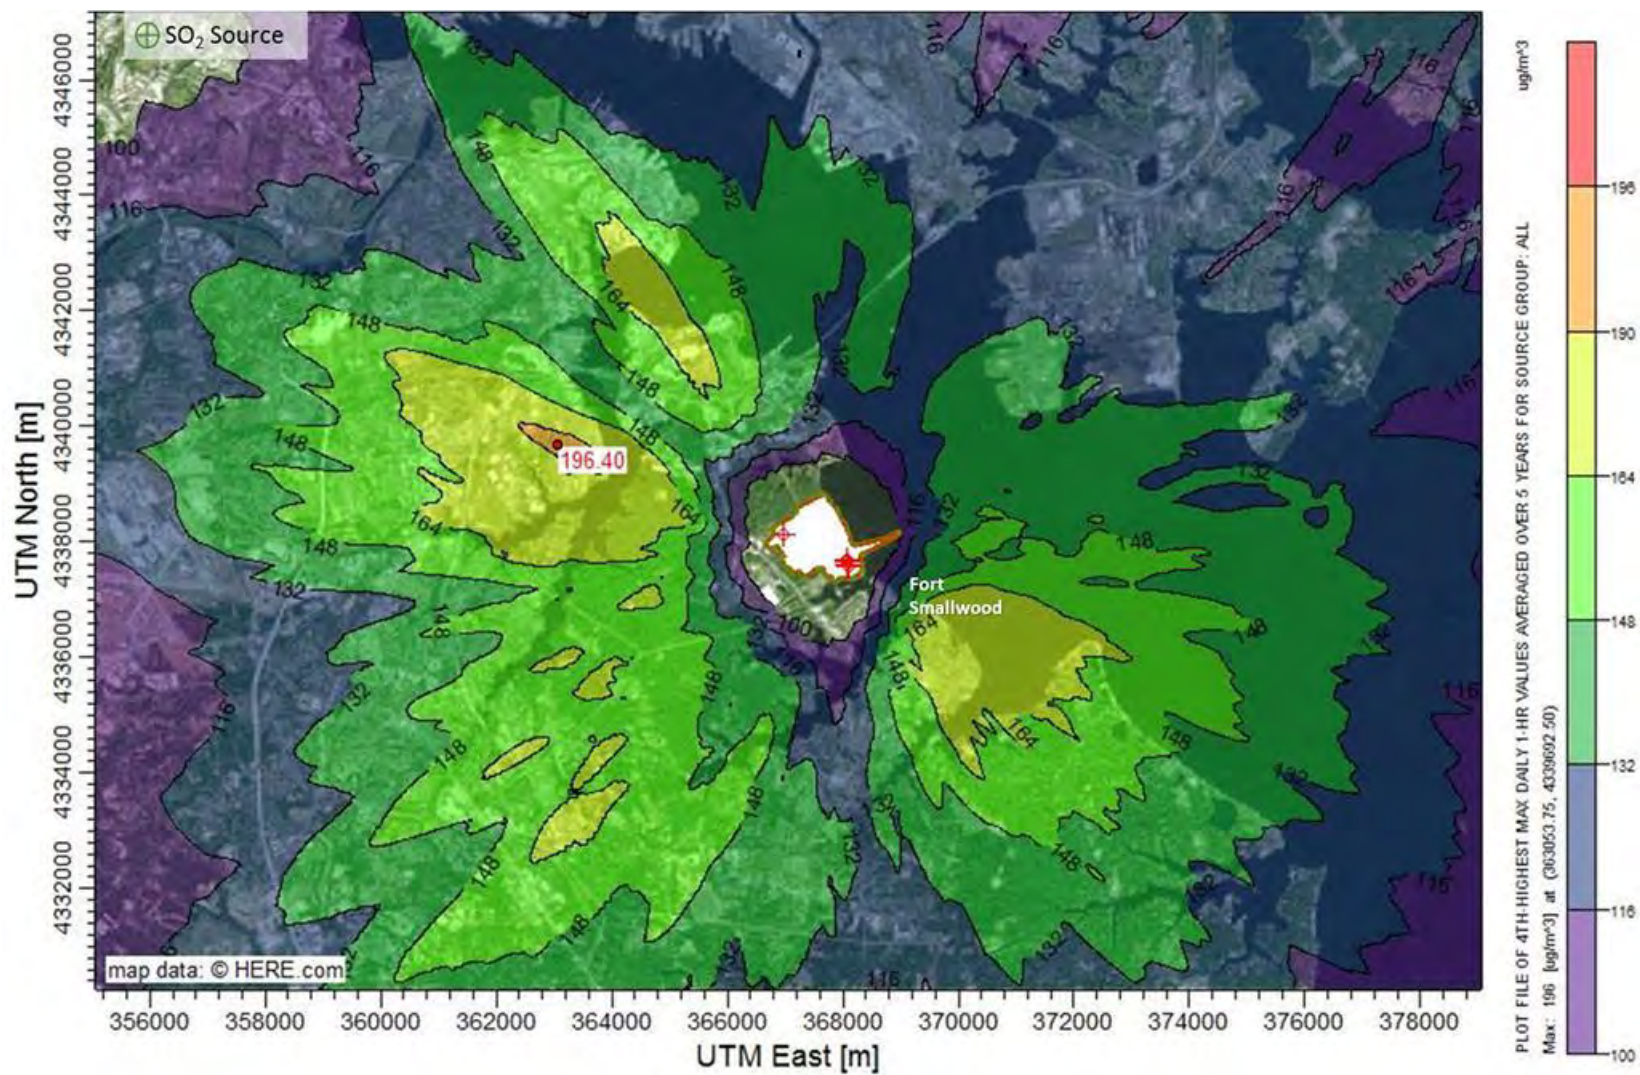

**Figure 5-1: 1-hour SO<sub>2</sub> Isopleths Showing the 99<sup>th</sup> Percentile Design Concentrations and Peak Impacts for the Entire Non-Attainment Area (Case 1)**

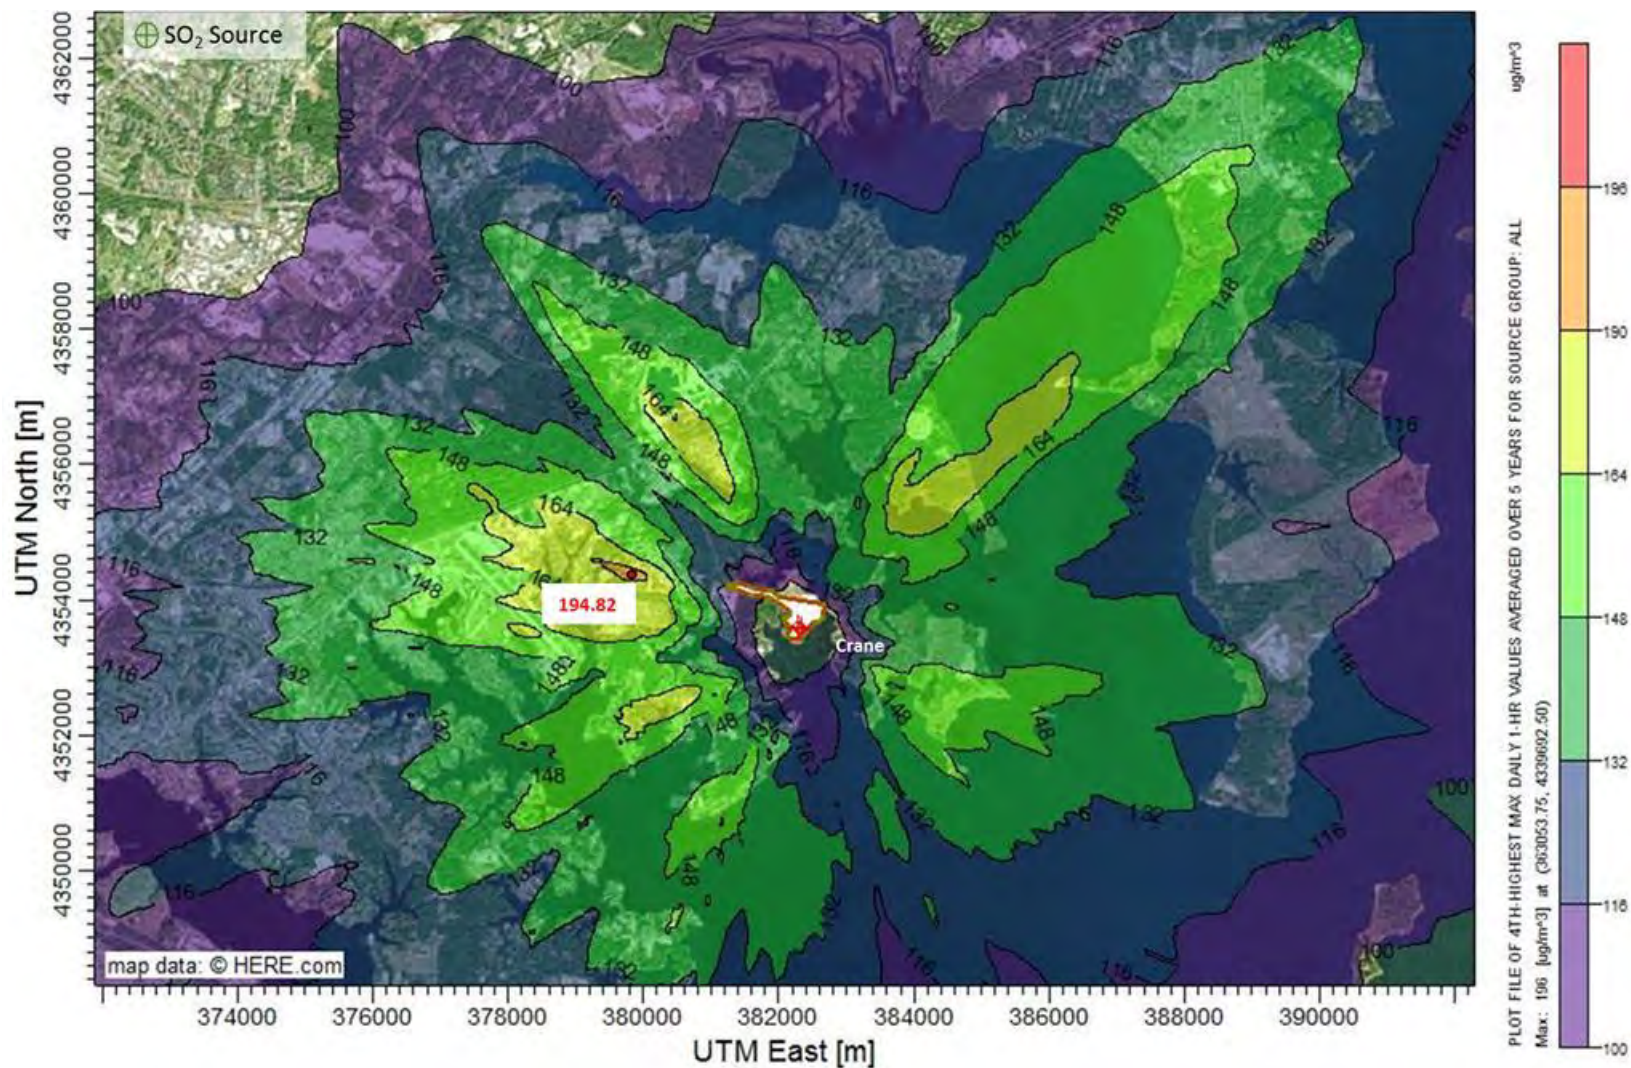

**Figure 5-2: 1-hour SO<sub>2</sub> Isopleths Showing the 99<sup>th</sup> Percentile Design Concentrations and Peak Impacts for the Entire Non-Attainment Area – Near Fort Smallwood Complex (Case 1)**

**Figure 5-3: 1-hour SO<sub>2</sub> Isopleths Showing the 99<sup>th</sup> Percentile Design Concentrations and Peak Impacts for the Entire Non-Attainment Area – Near Crane (Case 1)**

## 5.2 Model Results with Continuous Operation of Brandon Shores Only (Case 2)

The emission rates used in the 1-hour critical emission rate model runs for the Brandon Shores only emission case are presented in Table 5-4. The emission rates for Crane and Wheelabrator are the same as in Case 1. The emission rate for the Brandon Shores merged stack is equal to the total of emissions from both Brandon Shores and Wagner 3 from Case 1.

Figure 5-4 shows the 1-hour SO<sub>2</sub> isopleths for this compliance run with the peak impact (including background) of 194.59 µg/m<sup>3</sup> located approximately 1.4 km west of the Crane. Figures 5-5 and 5-6 show the isopleths and peak impact around Fort Smallwood Complex and Crane. A secondary maximum impact of 175.33 µg/m<sup>3</sup> is located about 3.7 km west-northwest of the Fort Smallwood Complex, as shown in Figure 5-5.

Tables 5-5 and 5-6 present the source culpability at the peak receptor near each plant for the controlling concentrations. The total concentration at the receptor is presented in the first row, while the remaining rows present the source contributions as concentrations in µg/m<sup>3</sup> and also as percentages of the total.

The non-attainment guidance issued by EPA in April 2014 allows for the consideration of longer emission averaging times that provide for comparable stringency with the critical emission values that can still be protective of the NAAQS. This analysis approach is discussed further in Section 6.

**Table 5-4: Emission Rates Used for Critical Value SO<sub>2</sub> NAAQS Compliance Modeling with Continuous Operation of Brandon Shores Only (Case 2)**

<b>Source</b>	<b>Critical Emission Value - SO<sub>2</sub> Emission Rates Modeled in Compliance Run (lb/hr)</b>	<b>Critical Emission Value - SO<sub>2</sub> Emission Rates Modeled in Compliance Run (g/s)</b>
Crane Unit 1 & 2	2,900	365.4
Brandon Shores Merged Stack	5,150	648.9
Wagner Unit 1	0	0.0
Wagner Unit 3	0	0.0
Wagner Unit 4	0	0.0
Wheelabrator	375	47.3

Note that the Brandon Shores merged emission rate is the same as the total of Brandon Shores merged plus Wagner 3 in Case 1.

**Table 5-5: Source Contributions for Peak Impact near Crane for Continuous Operation of Brandon Shores Only (Case 2)**

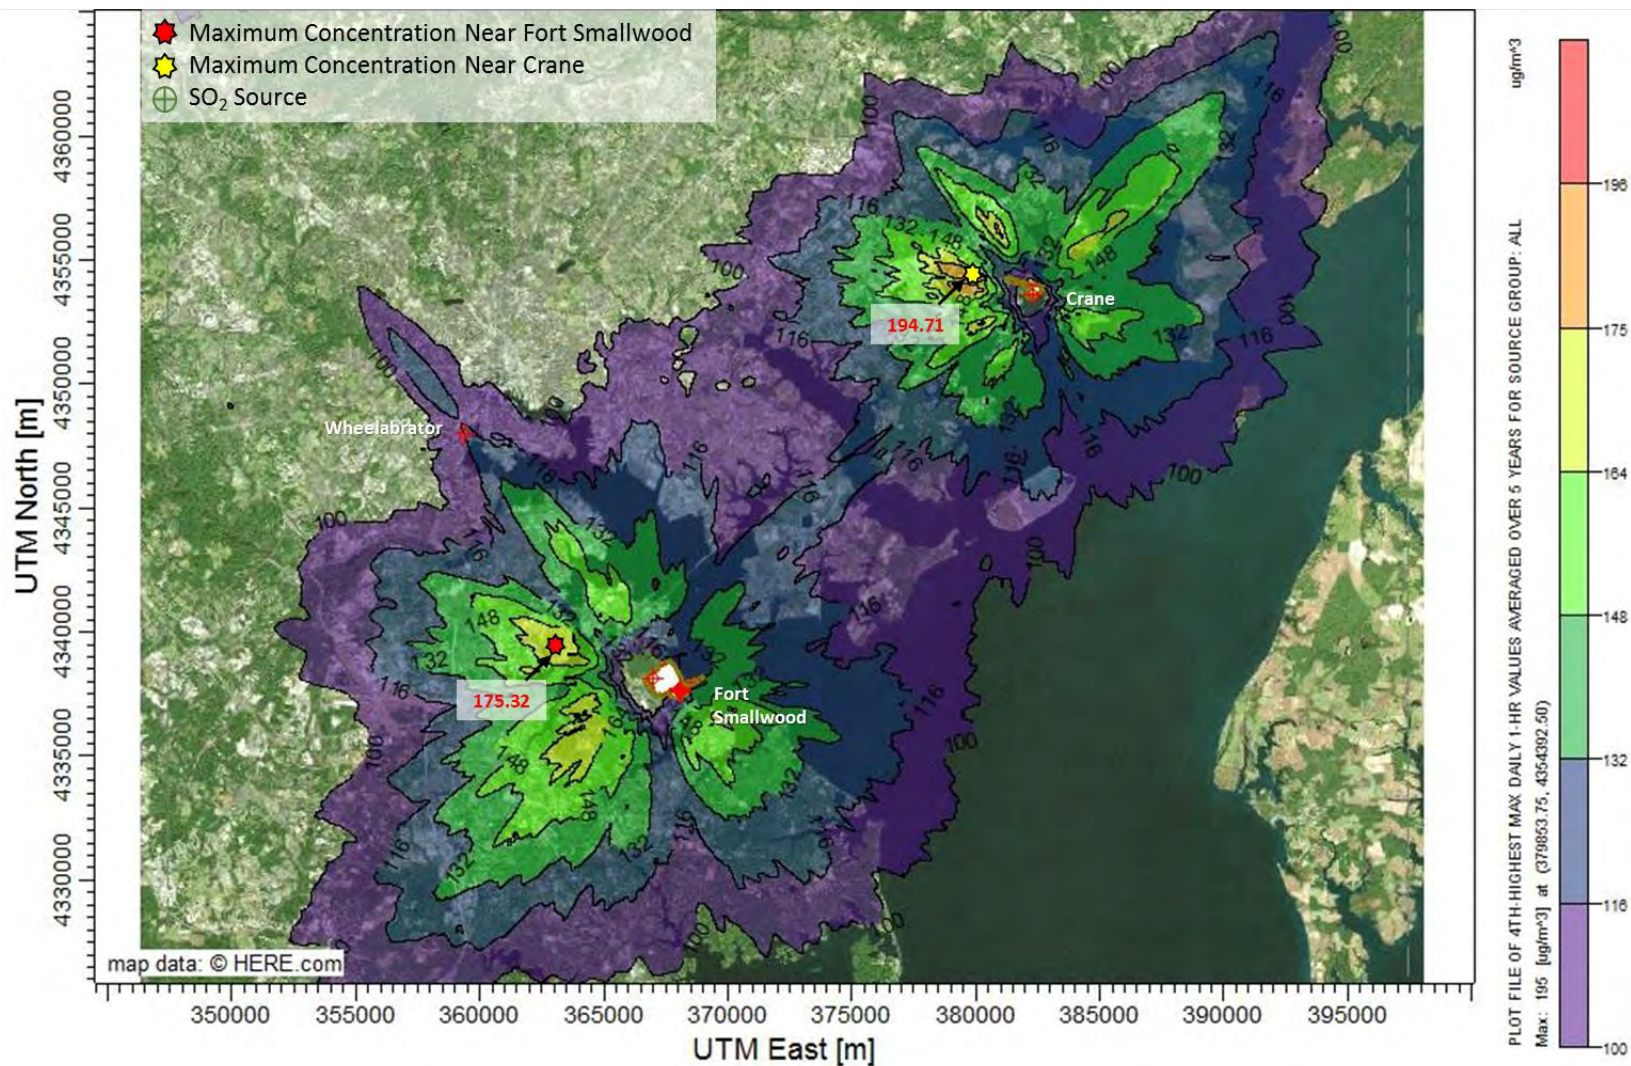

<b>Source</b>	<b>Concentration (<math>\mu\text{g}/\text{m}^3</math>)</b>	<b>Percent Contribution</b>

## 6. Proposed SO<sub>2</sub> Emission Limits for the Sources Located in the Baltimore, MD NAA

EPA's April 23, 2014 guidance for resolving SO<sub>2</sub> non-attainment areas acknowledges "that it may be possible in specific cases for states to develop control strategies that account for variability in 1-hour emissions rates through emission limits with averaging times that are longer than 1 hour, using averaging times as long as 30 days, but still provide for attainment of the 2010 1-hour SO<sub>2</sub> NAAQS." EPA's general expectation is that for infrequent periods of hourly emissions above the critical emission value, "these periods would be unlikely to have a significant impact on air quality, insofar as they would be very unlikely to occur repeatedly at the times when the meteorology is conducive for high ambient concentrations of SO<sub>2</sub>. EPA considers this option to be an "appropriate balance between providing a strong assurance that the NAAQS will be attained and maintained, while still acknowledging the necessary variability in source operations and the impairment to source operations that would occur under what could be in some cases an unnecessarily restrictive approach to constraining that variability" (emphasis added). Brandon Shores and Wagner Unit 3 are equipped with and operate with SO<sub>2</sub> emissions control devices. For such sources seeking alternate or longer-term emission limits, EPA's guidance notes that:

"Sources with emission control equipment may be especially prone to periodic occurrences of high emissions, arising on occasions when the control equipment is not operating or operating at reduced efficiency. Therefore, the EPA finds it advisable that longer-term average limits for sources that meet these limits through the use of emission control equipment be subject to supplemental limits that serve to constrain the frequency and/or magnitude of occasions of elevated emissions. Establishment of such supplemental limits as part of a longer-term averaging approach is especially important in cases with significant potential for frequent and/or high magnitude occasions of elevated emissions, including, but not limited to, sources using emissions control equipment."

Brandon Shores Units 1 and 2 are two coal-fired boilers that exhaust through a common stack. These units operate with FGD scrubbers. For these units, process upset conditions that could potentially result in infrequent elevated SO<sub>2</sub> emission spikes (e.g., loss of a spray pump in the flue gas desulfurization module) may be difficult to address within a one-hour period in a manner that restores operations to those that preceded the upset condition. These units are operated in a manner that avoids unplanned or abrupt changes in generating load. Consequently, establishing alternate SO<sub>2</sub> emission limits is appropriate for these sources.

Wagner Unit 3 is equipped with a dry sorbent injection (DSI) that reduces SO<sub>2</sub> emissions. During rare system malfunctions of the DSI injection, higher emissions of SO<sub>2</sub> can occur. Additionally, at maximum load, a condition that only occurs occasionally during more extreme electrical demand conditions, SO<sub>2</sub> removal may not be as effective due to lower retention time of the sorbent, so SO<sub>2</sub> emissions may be higher than normal for these hours. Given that these events are rather infrequent, Unit 3 will also pursue alternate SO<sub>2</sub> emission limits to account for these infrequent events.

Wagner Units 1 and 4 are fueled by oil, with Unit 1 using natural gas typically outside of the winter season. Due to various reasons, including economic, the regional transmission operator, PJM, rarely dispatches these units to serve the load. Historically, and future projections do not differ from the past, these units primarily operate when demand is highest (e.g., hot summer days and cold winter days). Because Wagner Units 1 and 4 emit SO<sub>2</sub> so infrequently, their emissions are similar in nature to occasional, peak SO<sub>2</sub> emissions from malfunctions of SO<sub>2</sub> controls, so establishing alternate SO<sub>2</sub> emission limits for these units would also be appropriate.

Lastly, alternate emission limits are also justified because of infrequent alignment of peak conditions. As discussed in Section 5.1 and 5.2, compliance (CEV) modeling was done for Case 1 (the continuous operation of Brandon Shores and Wagner Unit 3), and for Case 2 (the continuous operation of Brandon

Shores alone). As shown in Table 5-2 and Figure 5-1 of this report, the highest modeled concentration near Ft. Smallwood shows a plant lineup with Brandon Shores (Case 1) and Wagner (Case 1), with both sources operating at their continuous modeled emission rates during periods with a persistent east-southeast wind. Per Figure 4-13, the wind rose of the meteorological data used in this modeling study shows that winds from the east-southeast (assuming a 22.5-degree sector) occur less than 5 percent of the time. Talen Energy believes that the simultaneous occurrence of all of the controlling conditions is a low probability event that would warrant an alternate SO<sub>2</sub> emission limit for the sources.

For these reasons, Talen Energy proposes that attainment with the 1-hour SO<sub>2</sub> NAAQS in the Anne Arundel and Baltimore Counties, MD NAA, for H.A. Wagner and Brandon Shores can be assured via compliance with the use of 30-day rolling average limits calculated as discussed below. Talen Energy has elected to follow the procedure included in EPA's non-attainment guidance document, Appendix B. In general, EPA expects that any emission limit with an averaging time longer than 1 hour would need a downward adjustment to compensate for the loss of stringency inherent in applying a longer-term average limit. Discussions for the proposed SO<sub>2</sub> emission limits for each station are presented in the next five sub-sections followed by a summary of results from EPA's Appendix B modeling procedure in Section 6.6.

## 6.1 Crane Modeled SO<sub>2</sub> Emissions

Since Crane's SO<sub>2</sub> emissions are more of a single source, far from Ft. Smallwood, they will not require the use of Appendix B. As mentioned earlier in Section 3.1, PurENERGY will commit to a 1-hour emission rate of 2,900 lb/hr (365.3939 g/s) as a cap for C.P. Crane Units 1 and 2 combined. This constant emission rate of 2,900 lb/hr (365.3939 g/s) was used in all of the modeling demonstrations used in this report to support the Anne Arundel and Baltimore Counties, MD NAA SIP.

## 6.2 Appendix B Approach - Overview

As discussed in EPA's 2014 SO<sub>2</sub> nonattainment guidance document (Appendix B), the effect of infrequent emissions above the Critical Emission Value is outlined below:

"Exceedances of the SO<sub>2</sub> NAAQS occur when emissions from relevant sources are sufficiently high on occasions when the meteorology is conducive for those emissions to cause elevated SO<sub>2</sub> concentrations. An illustrative example would be a case in which a single source has a dominant impact on area concentrations, and the source only causes an exceedance at a particular location with light southwest winds with limited dispersion. In this example, the likelihood of an exceedance at that location will be a function of the likelihood of elevated emissions occurring during times of light southwest winds with limited dispersion. Stated more generally, the likelihood of an exceedance is a function of the likelihood of emissions being high when the meteorology is conducive for the source to cause an exceedance. By extension, the likelihood of a violation is a function of the likelihood of emissions being high on a sufficient number of times with meteorology conducive to having exceedances to have the average of the 99<sup>th</sup> percentile daily maximum values exceed the NAAQS. Viewed another way, the occasions when the meteorology is conducive for the source to cause an exceedance at a particular location are likely to be infrequent, and high concentrations are contingent on both emissions being sufficiently high and the meteorology being sufficiently conducive. The NAAQS itself is based on relatively rare occurrences, being based on the 99<sup>th</sup> percentile of daily maximum concentrations. Nevertheless, the point here is that the occurrence of high emissions will not cause an exceedance if it does not occur when meteorology is conducive to having an exceedance. Furthermore, a source with rare occurrences of high emissions and with much more frequent occurrences of moderate emissions is more likely to have moderate emissions on those occasions with meteorology conducive for exceedances, and the design value for the source may be more prone to reflect the moderate emissions than the high emissions."

EPA's 2014 SO<sub>2</sub> nonattainment guidance document establishes a procedure in Appendix B for showing that a longer-term emission limit (with a downward adjustment factor applied to the CEV based on a

projected distribution of emissions) can be protective of the 1-hour SO<sub>2</sub> NAAQS. The discussion on page 25 of this guidance further discusses this approach.

“Appendix B documents analyses that the EPA has conducted to evaluate the extent to which longer term average limits that have been adjusted to have comparable stringency to 1-hour limits at the critical emission value provide for attainment. In brief, while a longer term average limit as contemplated here would allow occasions when emissions exceed the critical emission value, the use of a lower limit compensates by requiring most values to be lower than they are required to be with a 1-hour limit at the critical emission value. The EPA expects that a common net result will be that the comparably stringent limit will provide a sufficient constraint on the frequency and magnitude of occurrences of elevated emissions (especially if supplemented with more direct limits on these occurrences) that a control strategy based on such limits would reasonably provide for attainment.”

Once the 1-hr critical emission value is established based on the traditional modeling approach (assuming constant operation), it can then be used as the baseline for establishing an emissions distribution throughout the year, including the variability described above, which will have a worst-case, long-term average emission rate below the CEV. To determine that emissions profile, historical emissions can be analyzed to determine a representative future emission scenario (inclusive of high and low operations and emissions) and then scaled as needed. A source could be expected to experience occasional hourly emission rates greater than the long-term (30-day) average emission limit or even the CEV with the likelihood that such infrequent emissions do not result in a NAAQS exceedance, as discussed above.

In their Appendix B of the 2014 SO<sub>2</sub> nonattainment guidance, EPA has outlined a procedure to conduct extensive modeling of a highly variable source as well as a site-specific modeling approach for demonstrating through a large number of modeling runs that a specific emissions distribution can be shown to protect the 1-hour SO<sub>2</sub> NAAQS. Establishing a longer-term average limit is most appropriate if the frequency and magnitude of such occasions of elevated emissions will be relatively low. This “Randomly Reassigned Emissions” (RRE) procedure is outlined below, followed by a discussion as to how this procedure was applied for the Brandon Shores Units 1 and 2.

1. Conduct dispersion modeling of the highest normal emissions to determine 1-hour CEV and use this result as a baseline for ensuring a lower, longer-term (i.e., rolling 30-day) limit would be considered an equivalently stringent limit.
2. Derive an estimate of the distribution of future emission from statistical analysis of a set of representative recent emissions data (i.e., CEMS) that reflects the emissions variability that the source is expected to exhibit in the future. This emission distribution can be expressed as a cumulative frequency distribution and can also be expressed as a set of discrete emission “bins” that approximate (or that conservatively provide a slightly higher set of emissions than) the cumulative emissions curve.
3. As needed, adjust the future emission values downward so that the entire set of modeling runs described below show NAAQS compliance and that the longer-term average of the emissions distribution is below the CEV. This could be an iterative process.
4. Create a large number (e.g., 100) of emission data sets (full years of hourly emissions data that reflects the emissions distribution) by randomly assigning hourly emission values from the scaled emissions.
5. Ensure the longer-term average emission rate derived from the 100 emission data sets, which could serve as the longer-term average limit, is less than the CEV value.
6. Conduct 100 sets of AERMOD simulation runs (with a 5-year meteorological data set in this case) using the randomly assigned hourly emission values to obtain the average 99<sup>th</sup> percentile of daily maximum concentrations. Create a 5-year average of the 99<sup>th</sup> percentile statistic at each receptor in preparation for the next step.

7. Compare the modeled design concentration obtained from the 100 model simulations (5-year averages) to the 1-hour SO<sub>2</sub> NAAQS. A successful outcome is that all of the 100 model simulations (5-year averages) show NAAQS compliance.

## 6.3 Brandon Shores Modeled SO<sub>2</sub> Emissions

### 6.3.1 Randomly Reassigned Emissions Analysis for Brandon Shores

A representative emission distribution was selected to be modeled for the randomly reassigned modeling runs based on the 2014-2016 actual emission dataset for Brandon Shores. The distribution accounts for the frequency and duration observed during actual plant operations, and this operation is expected to continue in a similar manner for future years. For conservatism, the “binned” or step-wise modeled hourly emissions were fit to a frequency curve that included slightly higher rates compared to the smoothed frequency distribution of the actual emissions. The 2014-2016 emission cumulative frequency plots were used in the analysis as the basis of the future emission bins to use in the 100 years of modeling. The future hourly emissions were computed by taking the 2014-2016 actual hourly heat input and multiplying them by 0.2 lb/MMBtu (the anticipated future emission rate). The maximum boiler ratings based on 2014-2016 data are 7,357 MMBtu/hr and 7,683 MMBtu/hr for Units 1 and 2, respectively. Figure 6-1 provides a comparison of the 2014-2016 hourly emissions to the future 1-hour CEV. Figure 6-2 shows a cumulative distribution of hourly emissions (2014-2016) and Figure 6-3 focuses on the top 10% of the cumulative frequency distribution compared to the future emission rates used in the longer term average (Appendix B) modeling.

For the modeling of Brandon Shores, two emission scenarios were selected (as discussed in Section 5). The first case included modeling the operation of both Brandon Shores and Wagner units, while the second case involves Brandon Shores and Wagner Units 1 and 4 (i.e., Wagner Unit 3 would not be operating) only as the results in Section 6.6.1 will show that Case 1 is the limiting case near Fort Smallwood. Section 6.4.1.1 discusses the former (Case 1) followed by a discussion of the analysis for Case 2 in Section 6.4.1.2.

#### 6.3.1.1 Randomly Reassign Emissions Analysis – Case 1

A total of 9 emission bins (provided in Table 6-1) were created with emission rates ranging from 1,000 lb/hr to 9,980 lb/hr for Brandon Shores Units 1 and 2 combined. Approximately 95% of the hours were set at or below a reference emission rate of 2,851 lb/hr, which is the critical emission value derived for Case 1. Although some of the time both of the Brandon Shores units will be off with zero emissions, the lowest emission bin was set at 1,000 lb/hr instead of zero lb/hr to be conservative.

The remaining 5% of the hours contain hourly emission rates greater than the CEV rate. The infrequent and higher magnitude emission rates that make up the 5% of the hours from Table 6-2 were modeled as groups, or events, that correspond to typical clustering of higher emission hours in terms of magnitude and frequency. Such prescribed events are characterized by a sequence of emissions with values greater than the short-term critical emission value lasting for pre-defined durations that are representative of the actual emission behavior associated with scrubber pump malfunctions. The historical data indicates a seasonal bias during the winter and summer periods, which correlates well with peak demand. The prescribed events in the Case 1 modeling of Brandon Shores have been designed to mimic this seasonality with a higher frequency during the winter and summer months. Of note is the highest value of 9,980 lb/hr, which is included to account for the rare potential of a full scrubber malfunction on one unit occurring until the unit is shut down (set at a duration of up to 3 hours and a frequency of once per year). As shown in Table 6-1, the weighted hourly emission rate (annual average of the emission bins) is equal to 1,925 lb/hr, which is also the target equivalent rolling 30-day NAAQS-compliant mass emission rate for Brandon Shores used in the RRE modeling for Case 1. The long-term emission rate represents a significant (32.5%) discount from the 1-hour CEV emission rate for Brandon Shores. Furthermore, the

rolling 30-day averaged emissions modeled would be higher than the annual average given the seasonality of the distribution for this source, thus the future limit is conservative.

The process for building 365-day randomly reassigned emission sets was repeated 100 times in order to develop the hourly emission files for the 100 AERMOD simulations. Appendix B of this report shows time series plots of the 100 simulated years of the hourly emissions for Case 1.

The 100 AERMOD simulations using randomly reassigned 1-hour emission rates for Brandon Shores were run in tandem with randomly reassigned 1-hour emission rates for Wagner Units 1, 3, and 4 along with a constant CEV 1-hour emission rate for Crane and Wheelabrator plus regional background (HU-Beltsville monitor for 2014-2016 as discussed in Section 4.7). Table 6-3 lists the long-term average emission rates (representative of a 30-day average) determined for each model simulation that are based on the average of the randomly reassigned hourly emission distribution for that simulation year. Some slight variability from the target equivalent rolling 30-day average of 1,925 lb/hr is expected given that the hourly-varying emissions are randomly assigned and the distribution may vary slightly from year to year.

#### 6.3.1.2 Randomly Reassign Emissions Analysis – Case 2

A total of 5 emission bins (provided in Table 6-4) were created with emission rates ranging from 2,500 lb/hr to 9,980 lb/hr for Brandon Shores Units 1 and 2 combined. Approximately 99.97% of the hours were set at or below a reference emission rate of 5,150 lb/hr, which is the critical emission value derived for Case 2. The critical emission value for Case 2 is the sum of the critical emission values for Brandon Shores Units 1 and 2 and Wagner Unit 3 from Case 1 (2,851 lb/hr + 2,299 lb/hr = 5,150 lb/hr). Similar to Case 1, a floor of 2,500 lb/hr was applied throughout the year to be conservative, even though the units will always have some down time.

The remaining 0.03% (3 hours) of the annual hours greater than the CEV rate consists of a single event that could last up to 3 hours (see Table 6-5) to account for the rare potential of a full scrubber malfunction on one unit occurring until the unit is shut down. This single annual event was modeled as a single event that could occur any time during the year. Note that all of the potential high emission events listed in Case 1, except this one, had magnitudes below the Case 2 CEV. As shown in Table 6-4, the weighted hourly emission rate (annual average of the emission bins) is equal to 3,860 lb/hr, which is also the target equivalent rolling 30-day NAAQS-compliant mass emission rate for Brandon Shores used in the RRE modeling for Case 2. The long-term emission rate represents a significant (25%) discount from the 1-hour CEV emission rate. Furthermore, the rolling 30-day averaged emissions modeled would be higher than the annual average given the seasonality of the distribution for this source, thus the future limit is conservative.

The process for building 365-day randomly reassigned emission sets was repeated 100 times in order to develop the hourly emission files for the 100 AERMOD simulations. Appendix C of this report shows time series plots of the 100 simulated years of the hourly emissions for Case 2.

The 100 AERMOD simulations using randomly reassigned 1-hour emission rates for Brandon Shores were run along with the randomly reassigned 1-hour emission rates for Wagner Units 1 and 4 (same as Case 1) with a constant CEV 1-hour emission rate for Crane and Wheelabrator plus regional background (HU-Beltsville monitor for 2014-2016 as discussed in Section 4.7). Table 6-6 lists the long-term average emission rates (representative of a 30-day average) determined for each model simulation that are based on the average of the randomly reassigned hourly emission distribution for that simulation year. Some slight variability from the target equivalent rolling 30-day average of 3,860 lb/hr is expected given that the hourly-varying emissions are randomly assigned and the distribution may vary slightly from year to year. The annual emissions limit for Brandon Shores is 11,019 tons/year, therefore the rolling 30-day rolling average limit of 3,860 lb/hr (equating to 16,907 tons/year) is not maintainable for more than three months of the year or the units would exceed their annual emissions limit.

### 6.3.2 Load-Varying Temperature and Velocity for Randomly Reassigned Emissions at Brandon Shores

To ensure that appropriate gas exhaust parameters (temperature and velocity) was accounted for in the Randomly Reassigned Emissions modeling for varying emission loads, representative values were calculated based on historical data for Brandon Shores and Wagner sources. Since Wagner Units 1 and 4 were assumed to be burning oil at full load conditions in all hours modeled, the temperature and velocities are relatively constant. As a result, full-load parameters were used across all emission rates for the Randomly Reassigned Emissions modeling.

For Brandon Shores Units 1 and 2, the gas exit temperature is relatively constant across operating loads due to the saturated plume from the scrubber, as shown in Figure 6-4. Therefore, a median temperature from 2014-2016 data of 323 Kelvin was used for all emissions bins.

The velocity exhaust parameter for Brandon Shores Units 1 and 2 does vary with operating load. The 2014-2016 hourly data for the combined units was divided into bins of 200 lb/hr increments for SO<sub>2</sub> emission rates. The median velocity corresponding to each 200 lb/hr emission bin was analyzed to determine if there are discrete groups that exist. Table 6-7 summarizes the median velocities for each 200 lb/hr bin. There appears to be 3 distinct groups that the velocities can be assigned to an operating load (minimum, mid and full). For emissions between 1,000 lb/hr and 1,399 lb/hr, a median velocity of 12.42 m/s was used, corresponding to minimum operating load. For emissions between 1,400 lb/hr and 2,799 lb/hr, a median velocity of 13.63 m/s was used for mid-load. For full load, emissions greater than 2,800 were modeled with a velocity of 14.41 m/s.

**Figure 6-4: Brandon Shores Combined Units 1 and 2 Exit Temperatures Versus SO<sub>2</sub> Emissions for 2014-2016**

**Table 6-7: Brandon Shores Combined Units 1 and 2 Median Velocities for Range of Emissions for 2014-2016**

Operating Load	Value	Bin 1	Bin 2	Bin 3	Bin 4	Bin 5	Bin 6	Bin 7	Bin 8	Average of the Velocities Per Operating Load (m/s)
Minimum	Lower Emission (lb/hr)	1000	1200							12.42
	Upper Emission (lb/hr)	1200	1400							
	Median Velocity (m/s)	12.18	12.665							
Mid	Lower Emission (lb/hr)	1400	1600	1800	2000	2200	2400	2600		13.63

## 6.4 Wagner Unit 3 Modeled SO<sub>2</sub> Emissions

### 6.4.1 Randomly Reassigned Emissions Analysis for Wagner Unit 3

A representative emission distribution was selected to be modeled for the randomly reassigned modeling runs based on the 2014-2016 actual emission dataset for Wagner Unit 3. The distribution accounts for the frequency and duration observed during that period. The magnitude of the past SO<sub>2</sub> emissions was based on a coal specification of  $\leq 1\%S$ , or  $\sim 1.63$  lb SO<sub>2</sub>/MMBtu). Due to the future reduction in sulfur content planned for Unit 3, the future SO<sub>2</sub> emission magnitudes used in the modeling were based on the observed hourly 2014-2016 heat inputs (MMBtu/hr), the future lower sulfur coal (1.1 lb SO<sub>2</sub>/MMBtu) and 30% control from DSI. The maximum heat input based on 2014-2016 data from Unit 3 was 2,740 MMBtu/hr. For conservatism, the “binned” or step-wise modeled hourly emissions were fit to a frequency curve that included slightly higher rates compared to the smoothed frequency distribution of the actual emissions. The 2014-2016 emission cumulative frequency plots were used in the analysis and were used for the basis of the emission bins to use in the 100 years of modeling. Figure 6-5 provides the 2014-2016 hourly emissions (adjusted for future operations at 1.1 lb/MMBtu and 30% DSI control) to the CEV. Figure 6-6 shows a cumulative distribution of hourly emissions (2014-2016) and Figure 6-7 focuses on the top 10% of the cumulative frequency distribution compared to the adjusted future operation emission rates used in the longer term average (Appendix B) modeling..

A total of 6 emission bins (provided in Table 6-8) were created with emission rates ranging from 1,500 lb/hr to 3,289 lb/hr for Wagner Unit 3. Approximately 96% of the hours were set at or below a reference emission rate of 2,299 lb/hr, which is the critical emission value derived for Case 1. The remaining 4% of the hours contain hourly emission rates greater than this reference rate. The infrequent and higher magnitude emission rates that make up the 4% of the hours from Table 6-9 were modeled as groups, or events, that correspond to potential malfunctions of SO<sub>2</sub> controls for Unit 3. Such prescribed events are characterized by a sequence of emissions with values greater than the short-term critical emission value lasting for pre-defined durations. There are 3 prescribed events based on the following assumptions, all of which would be at full load (max heat input) operation:

- Event 1: Occurs twice a year, each for a period of 72 hours. Emissions are based on 1.1 lb/MMBtu with 0% DSI control (24 hours) and 15% DSI control (48 hours),
- Event 2: Occurs once per month for a period of 8 hours. Emissions are based on 1.1 lb/MMBtu with 15% DSI control, and
- Event 3: Occurs once per month for a period of 8 hours. Emissions are based on 1.1 lb/MMBtu with 0% DSI control.

As shown in Table 6-8, the weighted hourly emission rate (annual average) of all the emission bins used in the NAAQS-compliant RRE modeling for Case 1 is equal to 1,904 lb/hr, which would be proposed as the rolling 30-day, mass emission limit for Wagner Unit 3. This long-term emission rate represents a discount of more than 17% from the 1-hour CEV emission rate. Furthermore, the rolling 30-day averaged emissions modeled would be higher than the annual average given the seasonality of the distribution for this source, thus the future limit is conservative.

The process for building 365-day randomly reassigned emission sets was repeated 100 times in order to develop the hourly emission files for the 100 AERMOD simulations. Appendix F of this report shows time series plots of the 100 simulated years of the hourly emissions.

The 100 AERMOD simulations using randomly reassigned 1-hour emission rates for Wagner 3 were run in tandem with randomly reassigned 1-hour emission rates for Brandon Shores, Wagner Units 1 and 4 along with a constant CEV 1-hour emission rate for Crane and Wheelabrator plus regional background (HU-Beltsville monitor for 2014-2016 as discussed in Section 4.7). Table 6-10 lists the long-term average

emission rates (representative of a 30-day average) determined for each model simulation that are based on the average of the randomly reassigned hourly emission distribution for that simulation year. Some slight variability from the target equivalent rolling 30-day average of 1,904 lb/hr is expected given that the hour-varying emissions are randomly assigned and the distribution may vary slightly from year to year

### 6.4.2 Load-Varying Temperature and Velocity for Randomly Reassigned Emissions at Wagner Unit 3

To ensure that appropriate gas exhaust parameters (temperature and velocity) were accounted for in the Randomly Reassigned Emissions modeling for varying emission loads, representative values were calculated based on historical data for Wagner Unit 3.

Figures 6-8 and 6-9 show the temperature versus adjusted emission rate and velocity versus adjusted emission rate, respectively. A temperature or velocity value would be assigned to a randomly reassigned emission rate bin based upon where the intersection of that emission rate meets the temperature or velocity data. To be conservative, we would select a temperature and velocity value that conservatively resides on the low end for a given randomly reassigned emission rate. For example, an emission rate of 1,500 lb/hr would yield a temperature of 394.44 K and a velocity of 24.107 m/s.

**Figure 6-8: Wagner Unit 3 Exit Temperatures Versus Future SO<sub>2</sub> Emissions for 2014-2016**

**Figure 6-9: Wagner Unit 3 Exit Velocity Versus Future SO<sub>2</sub> Emissions for 2014-2016**

## 6.5 Wagner Units 1 and 4 Modeled SO<sub>2</sub> Emissions

The current Title V permit for Wagner specifies that the oil burned shall not exceed 1% sulfur, which effectively limit SO<sub>2</sub> emissions from Unit 1 to 1,540 lb/hr and SO<sub>2</sub> emissions from Unit 4 to 4,550 lb/hr. Based on historical emissions from 2014-2016, these units do not typically operate more than 6 percent of the hours in any calendar year. To ensure emissions from these units are kept consistent with how they were modeled in this attainment demonstration Talen Energy proposes to limit the operating hours for both units to 438 hours per year (5%) each and to use of low-sulfur ( $\leq 0.3\%$ ) No. 6 oil, as discussed in Section 3.1.2. The equivalent SO<sub>2</sub> emission rates for modeling would be 480 lb/hr (Unit 1) and 1,350 lb/hr (Unit 4). These new maximum 1-hour emission rates represent a significant reduction (approximately 70%) from the current emission limits.

As described above, the normal (95<sup>th</sup> percentile) operations of these units is to be off, and as a result of the infrequent operation of Units 1 and 4, the critical emission values for these units were set to zero for the 1-hour CEV modeling for the area (both Case 1 and Case 2).

Consistent with the Appendix B of the EPA's April 23, 2014 guidance, which was used for the normally operating sources (Brandon Shores and Wagner Unit 3), emissions from Wagner Units 1 and 4 were included as other high emission events in this Appendix B modeling for both Case 1 and Case 2. In other words, these infrequent emissions above the CEV were treated the same as the infrequent emissions above the CEV for the normally operating units.

### 6.5.1 Randomly Reassigned Emissions Analysis for Wagner Unit 1

As described in the modeling protocol, Units 1 and 4 primarily operate during the winter (December-March) and summer (June-August) months and the RRE distributions for these sources include more operating hours during these periods. Based on recent 3-year historical data from 2014-2016, Unit 1 did not operate more than 12 hours on oil during the shoulder seasons of April-May and September-November, but Unit 4 operated 17 hours during the shoulder seasons; therefore, both units were conservatively modeled for 20 hours of operation for each month. The maximum heat input based on 2014-2016 data for Unit 1 was 1,491 MMBtu/hr. The proposed RRE distribution for Unit 1 is summarized in Table 6-11. To account for possible operation of these sources in the shoulder seasons, the units were assumed to operate in every month of the year in order to add more conservatism to the modeling analysis and to avoid seasonal operational limits on these units. Note that in the shoulder seasons, the unit was modeled running on oil for 20 hours per month, while the modeling assumed 40 hours per month during summer and winter months. The unit was modeled with two events of operations; the first event was 20 consecutive hours (occurring either once or twice per month), while the second event had a duration of 96 consecutive hours. The second event was simulated to occur only twice a year, once each in the winter and summer months. The total number of oil operating hours per year for Units 1 was modeled at 572 hours. This number of hours is conservatively higher than the proposed 438 operating hours per year limit. As a reminder, Wagner 1 is capable of operating on natural gas or fuel oil and most recently operated primarily on natural gas.

The process for building 365-day randomly reassigned emission sets was repeated 100 times in order to develop the hourly emission files for the 100 AERMOD simulations. Appendix D of this report shows time series plots of the 100 simulated years of the hourly emissions.

For all of the 572 operating hours that Unit 1 was modeled in the 100-iteration Case 1 RRE runs, full-load emissions (480 lb/hr) and stack parameters were used. This added a significant level of conservatism into the modeling analysis as these units typically ramp up and down, or may sit at part load depending on demand. Furthermore, the operating times for both Units 1 and 4 were synchronized in the modeling; therefore, if one of the units was running, then the other was also simulated to emit for that same period. Since Unit 1 operations (i.e., high emission events) were added to the RRE simulations for all the other sources (Brandon Shores, Wagner Unit 3), which were modeled as being in operation at all times, the RRE modeling is very conservative.

**Table 6-11: Events and Corresponding Durations Modeled for Unit 1 Per Month for 100-Iterations of RRE Runs**

Month	RRE Event 1	RRE Event 2**

	<b>380</b>	<b>192</b>
<b>Total</b>	<b>572</b>	

\*\* Event 2 occurred twice per year with a 96-hour event in the highlighted winter and summer months. The month for which this 96-hour event was triggered within these seasons was randomly varied for each RRE simulation run.

## 6.5.2 Randomly Reassigned Emissions Analysis for Wagner Unit 4

As described in the modeling protocol, Units 1 and 4 primarily operate during the winter (December-March) and summer (June-August) months and the RRE distributions for these sources include more operating hours during these periods. Based on recent 3-year historical data from 2014-2016, Unit 1 did not operate more than 12 hours on oil during the shoulder seasons of April-May and September-November, but Unit 4 operated 17 hours during the shoulder seasons; therefore, both units were conservatively modeled for 20 hours of operation for each month. The maximum heat input based on 2014-2016 data for Unit 4 was 4,197 MMBtu/hr. The proposed RRE distribution for Unit 4 is summarized in Table 6-12. To account for possible operation of these sources in the shoulder seasons, the units were modeled in every month of the year in order to add more conservatism to the modeling analysis and to avoid seasonal operational limits on these units. Note that in the shoulder seasons, the unit was modeled to be oil-fired for 20 hours for each month. The unit was modeled with two events of operations; the first event is 20 consecutive hours (occurring once in shoulder seasons and twice in active seasons), while the second event had a duration of 96 consecutive hours. The second event was simulated to occur only twice a year, once each in the winter and summer months. These events are identical to those identified for Unit 1 in Section 6.5.1. The total number of operating hours for Units 4 was simulated to be 572 hours per year.

The process for building 365-day randomly reassigned emission sets was repeated 100 times in order to develop the hourly emission files for the 100 AERMOD simulations. Appendix E of this report shows time series plots of the 100 simulated years of the hourly emissions.

For all of the 572 operating hours that Unit 4 was modeled in the 100-iteration RRE runs, full-load emissions (1,350 lb/hr) and stack parameters were used. This adds a significant layer of conservatism into the modeling analysis as these units typically ramp up and down. Furthermore, the operating times for both Units 1 and 4 were synchronized in the modeling; therefore if one of the units was running, then the other unit was simulated to emit for that same period.

**Table 6-12: Events and Corresponding Durations Modeled for Unit 4 Per Month for 100-Iterations of RRE Runs**

Month	RRE Event 1	RRE Event 2**
January	40	96
February	40	
March	40

	<b>380</b>	<b>192</b>
<b>Total</b>	<b>572</b>	

\*\* Event 2 occurred twice per year with a 96 hour event in the highlighted winter and summer months. The month for which this 96-hour event was triggered within these seasons was randomly varied for each RRE simulation run.

## 6.6 Results of the RRE Modeling

### 6.6.1 Case 1 Results

As described above, 100 AERMOD simulations were run using randomly reassigned 1-hour emission rates for Brandon Shores (merged stack) and Wagner Units 1, 3, and 4 along with a constant CEV 1-hour emission rates for Crane and Wheelabrator plus regional background (HU-Beltsville monitor for 2014-2016 as discussed in Section 4.7). These 100 modeling runs, with 5-year running averages of the 99<sup>th</sup> percentile peak daily 1-hour maximum at each receptor, all resulted in design concentrations that comply with the NAAQS.

The highest 5-year average 99<sup>th</sup> percentile daily maximum SO<sub>2</sub> concentration of the 100 model simulations, for Case 1, was 194.91 µg/m<sup>3</sup> (occurred in simulation run 87) and is in compliance with the NAAQS. Figure 6-10 shows the design concentration isopleths for RRE simulation 87 with the highest impact located approximately 3.6 km to the west-northwest of the Fort Smallwood Complex. A secondary maximum impact of 194.34 µg/m<sup>3</sup> is located about 1.4 km west of Crane, as shown in Figure 6-10.

Tables 6-13 and 6-14 present the source culpability at the peak receptor near each plant for the controlling concentrations of RRE simulation run 87. The total concentration at the receptor is presented in the first row, while the remaining rows present the source contributions as concentrations in µg/m<sup>3</sup> and also as percentages of the total. A visual representation of these source capability results along with the controlling CEV peak impact receptors near Fort Smallwood and Crane are shown in Figures 6-11 and 6-12, respectively.

Appendix G provides a table of the highest 5-year average 99<sup>th</sup> percentile daily maximum SO<sub>2</sub> concentrations for each simulation run for Case 1.

As part of EPA Region 3's initial review and comments on this modeling demonstration, they provided additional statistics and observations based on the proposed RRE modeling approach. For the controlling RRE simulation run 87, EPA Region 3 provided an hour of day plot (Figure 6-13) of the combined Fort Smallwood hourly emission and included the following comment:

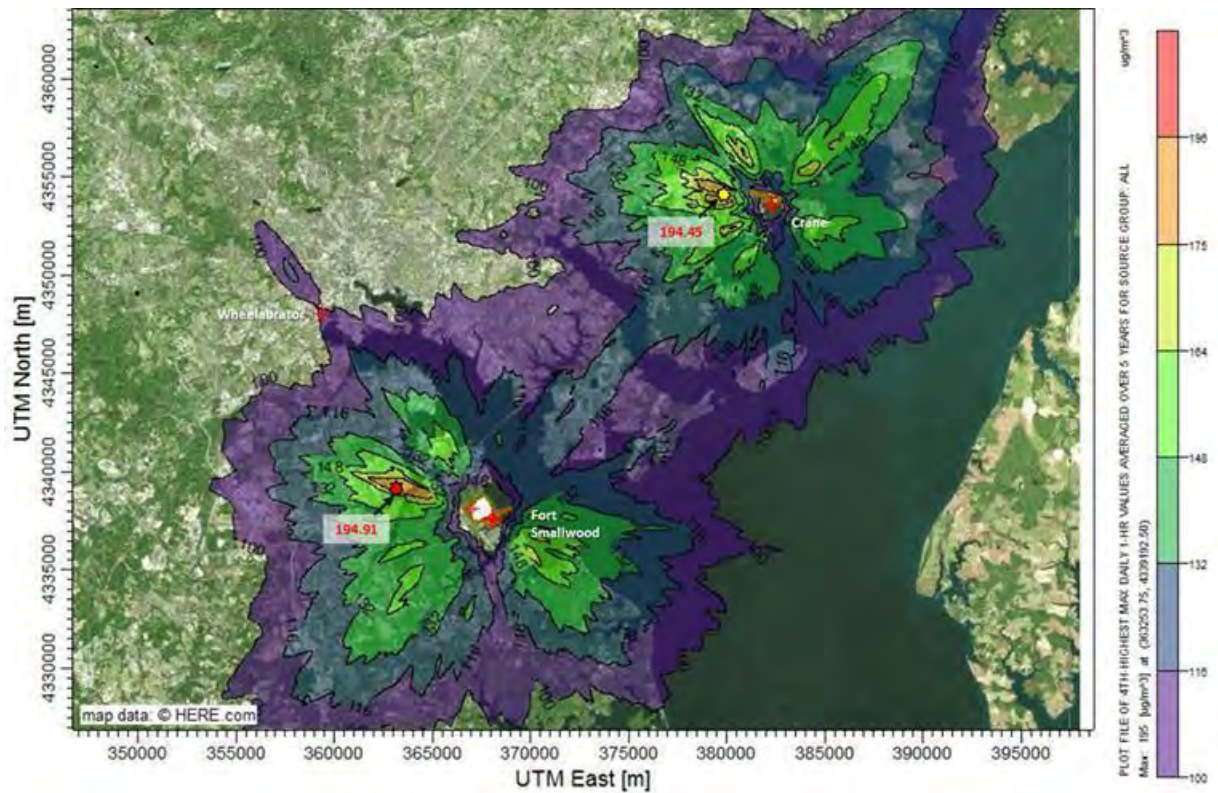

“... hourly model emission rates exceeding the combined CEV-1 values for Brandon Shores and Wagner Unit 3 are occurring during the day time hours when peak model concentrations are expected to occur and demonstrate that emissions are not being overly isolated to overnight hours when the model shows peak concentrations are not expected to occur. Note that the average combined hourly emissions are below the combined CEV-1 for Brandon Shores and Wagner Unit 3 (5,150 lbs/hr). Based on the standard deviation, it appears a substantial number of hours during the RRE simulations have combined emissions below the combined CEV; approximately 87% of the hours during the simulation are below this emission threshold. As noted in AECOM's report, the modeled hourly emissions are based on historic emission rates at Fort Smallwood and include a little over 12% of the hours where emissions exceed the combined CEV for Brandon Shores and Fort Smallwood.”

Table 6-15 provides a comparison of the model concentrations at the peak receptor location for the Case 1 CEV run and the Case 1 RRE simulation run 87. EPA Region 3 provided the following assessment based on the results from this table:

“The peak receptor locations, and yearly distributions of 4<sup>th</sup> high concentrations are remarkably similar given that the bulk of the RRE Case 87 hours had combined Fort Smallwood emissions below the CEV-1 limit (5,150 lbs/hr). This appears to support the RRE methodology in regards to establishing the proposed emission rates that will meet the 1-hour SO<sub>2</sub> NAAQS.”

Because of the voluminous amount of data used in support of these calculations, these data are not included in this report, but are rather included with the modeling files provided to MDE and EPA.

## 6.6.2 Case 2 Results

As described above, 100 AERMOD simulations were run using randomly reassigned 1-hour emission rates for Brandon Shores (merged stack), Wagner Units 1 and 4, with a constant CEV 1-hour emission rate for Crane and Wheelabrator plus regional background (HU-Beltsville monitor for 2014-2016 as discussed in Section 4.7). These modeling runs, with 5-year running averages of the 99<sup>th</sup> percentile peak daily 1-hour maximum at each receptor, all resulted in design concentrations that comply with the NAAQS.

The highest 5-year average 99<sup>th</sup> percentile daily maximum SO<sub>2</sub> concentration of the 100 model simulations for Case 2, was 196.09 µg/m<sup>3</sup> (occurred in simulation run 97) and is in compliance with the NAAQS. Figure 6-13 shows the design concentration isopleths for RRE simulation 97 with the highest

impact located approximately 1.4 km to the west of Crane. A secondary maximum impact of 166.70  $\mu\text{g}/\text{m}^3$  is located about 3.5 km southwest of the Fort Smallwood Complex, as shown in Figure 6-13. PM<sub>2.5</sub>

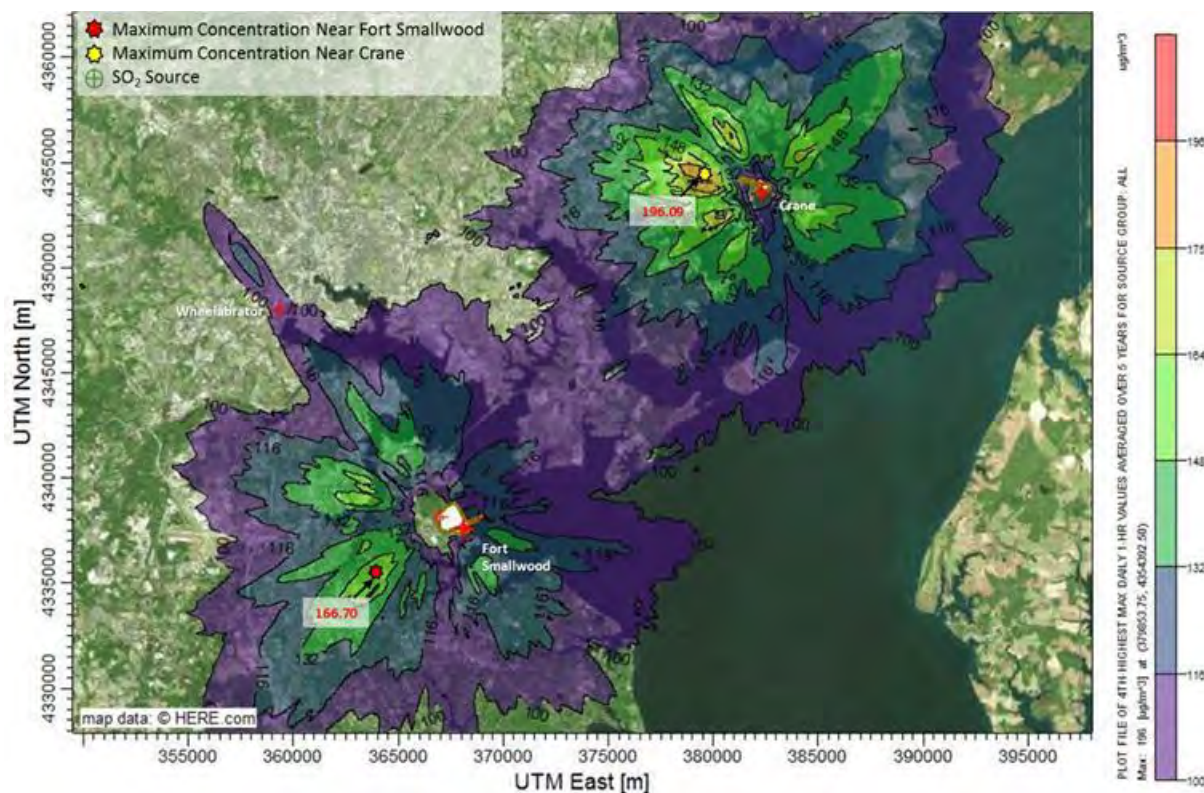

Tables 6-15 and 6-16 present the source culpability at the peak receptor near each plant for the controlling concentrations of RRE simulation run 87. The total concentration at the receptor is presented in the first row, while the remaining rows present the source contributions as concentrations in  $\mu\text{g}/\text{m}^3$  and also as percentages of the total. A visual representation of these source capability results along with the controlling CEV peak impact receptors near Fort Smallwood and Crane are shown in Figures 6-14 and 6-15, respectively.

Table 6-18 provides a comparison of the model concentrations at the peak receptor location for the Case 2 CEV run and the Case 2 RRE simulation run 97. The peak receptor for both runs is the same and as shown in Section 6.6.1 for Case 1, the yearly distributions of the 4<sup>th</sup> high concentrations are similar.

Appendix H provides a table of the highest 5-year average 99<sup>th</sup> percentile daily maximum SO<sub>2</sub> concentrations for each simulation run for Case 2.

Because of the voluminous amount of data used in support of these calculations, these data are not included in this report, but are rather included with the modeling files provided to MDE and EPA.

### 6.6.3 Maximum 30-day Rolling Averages for Brandon Shores and Wagner Unit 3

After determining that all of the RRE runs demonstrate attainment of the SO<sub>2</sub> NAAQS, Talen calculated a 30-day average emission rate across the full range of emission rates input into the RRE runs that could serve as a protective limit. As discussed in Section 6.4.1.1, high emission events could potentially occur during the winter or summer months, corresponding with high load demand for Brandon Shores. The 30-day rolling average permit limit would therefore need to account for this seasonality by taking the sum of the total high emissions and the total of “non-event” (i.e., normal) emissions (values at or below the CEV) for a summer or winter month input into the RRE modeling and dividing that by the number of hours in a 30-day period (720 hours). Brandon Shores is simulated in the RRE modeling to have 55 hours of high emission events in the month of January, leaving 665 hours for non-event emissions in a 30-day period. The sum of the high emissions for 55 hours and the sum of non-event emissions of the remaining hours divided by 720 hours results in a maximum 30-day average of 1,927.4 lb/hr. This maximum value of 1,927.4 lb/hr would be the proposed 30-day rolling average permit limit for Brandon Shores.

The same maximum 30-day calculation can be applied to Wagner Unit 3. During two months of every year all three of the prescribed high emission events outlined in Table 6-9 would occur. This would total 88 hours of high emission events in either of these months, leaving 632 hours for non-event emission in a 30-day period. The sum of the high emission for the 88 hours and the sum of the non-event emissions of the remaining hours divided by 720 hours results in a maximum 30-day average of 1,933.55 lb/hr.

The sum of the maximum 30-day average emission limits for Brandon Shores and Wagner Unit 3 from Case 1 (3,860 lb/hr) would conservatively be set as the 30-day rolling average limit for Brandon Shores-only operations (Case 2).

## 7. Summary of Critical and Longer-Term Emission Rates

Table 7-1 provides a summary of the 1-hour and the equivalent longer-term average emission rates, as appropriate, for each station modeled that will ensure compliance with the 1-hour SO<sub>2</sub> NAAQS in the Anne Arundel and Baltimore County, MD non-attainment area. These federally enforceable proposed limits for Crane, Brandon Shores and Wagner units listed in Table 7-1 have been established based on the extensive modeling discussed in Sections 5 and 6 of this report. The proposed future SO<sub>2</sub> emission limits are significantly lower than the current SO<sub>2</sub> emission limits for each plant. For Crane, the proposed 1-hour SO<sub>2</sub> emission limit is a 78% emission reduction from the current limit. The proposed not to exceed 1-hour limits for Wagner Unit 1 and 4 are both near 70% of their current SO<sub>2</sub> emission limits and Wagner Unit 3's proposed not to exceed 1-hour limit is 28% lower than the current limit.

The lower SO<sub>2</sub> emission limits at Wagner are due in large part to the future operation changes that will be in place by January 2021. These include:

- Unit 1 will operate no more than 5% of the year (438 hours) on low-sulfur (0.3%) No. 6 oil (otherwise it will fire on natural gas),
- Unit 3 will burn lower-sulfur coal, such as New Source Performance Standard (NSPS) compliant coal (1.1 lb SO<sub>2</sub>/MMBtu);
- Implementation of a specialized sorbent is expected to improve SO<sub>2</sub> control efficiency of the dry sorbent injection system for Wagner Unit 3, achieving a 30% SO<sub>2</sub> reduction, and
- Unit 4 will operate no more than 5% of the year (438 hours) on low-sulfur (0.3%) No. 6 oil.

For Brandon Shores Units 1 and 2 and Wagner Unit 3, the emission distribution used in the RRE modeling for Case 1 (and Case 2 for Brandon Shores) conservatively assumed these units are continuously operating for every hour of the year at various emission rates and the 30-day average emission limits are calculated from that emissions distribution (See Section 6.6.3). To be clear, the maximum 30-day rolling average limits would apply to emissions averaged over all 720 hours in any rolling 30-day period, which can include hours with zero emissions. The limits on the fraction of time that the emissions can exceed the CEV provides sufficient constraints to assure NAAQS compliance.

Note that in Table 7-1 Wagner 3 has a 30-day average limit, but Brandon Shores does not. Wagner 3's limit is based on its maximum emissions modeled in Case 1 when Brandon Shores was also operating. Brandon Shores is effectively limited by the combined coal unit limit (3,860 lb/hr) 1) because it is equal to the Brandon Shores 30-day average emissions from Case 2 (only Brandon Shores operating), and 2) because it is equal to the sum of the Brandon Shores and Wagner Unit 3 emissions that passed in Case 1. In other words, within 30-day average periods, if Wagner 3 is not operating, Brandon Shores emissions are limited to 3,860 lbs/hr, and if Wagner 3 is operating, Brandon Shores emissions are limited to the difference between 3,860 lbs/hr and Wagner 3's emissions. Therefore, whether Wagner Unit 3 is operating or not, Brandon Shores is limited by the combined coal unit 30-day average emission limit of 3,860 lb/hr, as summarized in Table 7-1.

Not to exceed 1-hour average emission limits for Brandon Shores and Wagner sources are based on the highest 1-hour average emission limit included in the RRE (EPA's Appendix B approach) modeling for Cases 1 and 2. For Brandon Shores, the highest 1-hour average value modeled was 9,980 lb/hr and for Wagner 3 it was 3,289 lb/hr. Wagner Units 1 and 4 were modeled as either "on" at full-load or "off" with highest 1-hour SO<sub>2</sub> emission rates of 480 lb/hr and 1,350 lb/hr, respectively.

With the exception of the Brandon Shores-only scenario, the percentage of hours of high emissions that can exceed the established CEV values (i.e., "high emission events") is based on the use of a 5% "rule-of-thumb" as approved in an Illinois SO<sub>2</sub> emission limitation rule<sup>19</sup>. Brandon Shores and Wagner Units 1

<sup>19</sup> Available at [http://ilrules.elaws.us/iac/t35\\_pt214\\_sec.214.301](http://ilrules.elaws.us/iac/t35_pt214_sec.214.301); see Section 214.603(e) for Powerton.

and 4 were modeled with high emission events occurring approximately 5% of the hours, while Wagner Unit 3 was lower at around 4%. The CEV for the Brandon Shores-only scenario was high enough that only one, very unlikely, high emission event lasting only 3 hours was modeled in the RRE runs; therefore, the limit of time over the CEV was set at 3 hours.

The extensive modeling presented in this report and in the modeling archive, consisting of 200 5-year periods, demonstrates attainment with the NAAQS in the Anne Arundel and Baltimore Counties, MD non-attainment area.

**Table 7-1: Proposed SO<sub>2</sub> Enforceable Limits**

<b>Source</b>	<b>Current SO<sub>2</sub> Emission Limit</b>	<b>Proposed Additional SO<sub>2</sub> Emission Limits (2021 and Beyond)</b>
C.P. Crane	3.5 lb/MMBtu 13,055 lb/hr (1-hr Avg.)	2,900 lb/hr (1-hr Avg.)
Brandon Shores Units 1 and 2 and Wagner Unit 3 (Combined coal units)	N/A	3,860 lb/hr (30-day Average)
Brandon Shores Units 1 and 2 (combined) <sup>(1)</sup>	5,392 tons/year (Unit 1) 5,627 tons/year (Unit 2) Not to Exceed 1.2 lb/MMBtu	Emissions Above 2,851 lb/hr (1-hr Avg.) allowed up to 435 hours annually when Wagner 3 is operating; Emissions Above 5,150 lb/hr (1-hr Avg.) allowed up to 3 hours annually when Wagner 3 is not operating; Not to Exceed 9,980 lbs/hr (3-hr period per year)
Wagner Unit 1	1,540 lb/hr (1-hr Avg.)	Operation up to 438 hours annually (No. 6 Fuel Oil); Not to Exceed 480 lb/hr 1-hr Avg.
Wagner Unit 3	4,550 lb/hr (1-hr Avg.)	1,904 lb/hr (30-day Avg.); Emissions Above 2,299 lb/hr (1-hr Avg.) allowed up to 336 hours annually; Not to Exceed 3,289 lb/hr (1-hr Avg.)
Wagner Unit 4	4,550 lb/hr (1-hr Avg.)	Operation up to 438 hours annually (No. 6 Fuel Oil); Not to Exceed 1,350 lb/hr 1-hr Avg.

(1) Separate 30-day average not required as it is included in the combined coal unit 30-day limit.

## Technical Support Document for Final Designation

### Maryland Area Designations for the 2010 SO<sub>2</sub> Primary National Ambient Air Quality Standard

#### Summary

Pursuant to section 107(d) of the Clean Air Act (CAA), the U.S. Environmental Protection Agency (EPA, or the Agency) must designate areas as either “unclassifiable,” “attainment,” or “nonattainment” for the 2010 1-hour sulfur dioxide (SO<sub>2</sub>) primary national ambient air quality standard (NAAQS). Section 107(d) of the CAA defines a nonattainment area as one that does not meet the NAAQS or that contributes to a violation in a nearby area, an attainment area as any area other than a nonattainment area that meets the NAAQS, and an unclassifiable area as any area that cannot be classified on the basis of available information as meeting or not meeting the NAAQS.

July 2, 2016 is the deadline for the EPA to designate certain areas established by the U.S. District Court for the Northern District of California. This deadline is the first of three deadlines established by the court for the EPA to complete area designations for the 2010 SO<sub>2</sub> NAAQS. This deadline applies to a certain area in Maryland because one emission source meets the conditions of the court’s order.

Maryland submitted a designation recommendation on April 19, 2011, and an updated recommendation on November 20, 2015. On April 14, 2016, Maryland submitted an alternative model request for use of a non-regulatory default/beta Adjust U\* option in their modeling analyses for the area surrounding Wagner. On April 19, 2016, Maryland submitted additional modeling analyses and information. Table 1 below lists Maryland’s recommendations and identifies the counties in Maryland that the EPA is designating in order to meet the July 2, 2016, court-ordered deadline. These final designations are based on an assessment and characterization of air quality through ambient air quality data, air dispersion modeling, other evidence and supporting information, or a combination of the above.

**Table 1. Maryland’s Recommended and EPA’s Final Designations**

Area	State’s Recommended Area Definition	State’s Recommended Designation	EPA’s Final Area Definition	EPA’s Final Designation
<u>Anne Arundel County and Baltimore County</u> <sup>1</sup>	Area boundary not provided	Attainment	Portions of Anne Arundel and Baltimore Counties that are within 26.8 kilometers of Herbert A. Wagner’s Unit 3 stack, which is located at	Nonattainment

<sup>1</sup> The EPA is finalizing our intended designation of nonattainment. However, the EPA is modifying the intended area definition from portions of Anne Arundel and Baltimore Counties that are with 35.5 kilometers of Wagner’s

			39.17765N latitude, 76.52752W longitude (Anne Arundel County and Baltimore County, MD)	
Baltimore City <sup>2</sup>	Baltimore City	Unclassifiable	Same as State's Recommendation (Baltimore City, MD)	Unclassifiable/ Attainment

### Background

On June 3, 2010, the EPA revised the primary (health based) SO<sub>2</sub> NAAQS by establishing a new 1-hour standard at a level of 75 parts per billion (ppb) which is met at an ambient air quality monitoring site when the 3-year average of the 99th percentile of 1-hour daily maximum concentrations does not exceed 75 ppb. This NAAQS was published in the *Federal Register* on June 22, 2010 (75 FR 35520), and is codified at 40 CFR 50.17. The EPA determined this is the level necessary to protect public health with an adequate margin of safety, especially for children, the elderly, and those with asthma. These groups are particularly susceptible to the health effects associated with breathing SO<sub>2</sub>. The two prior primary standards of 140 ppb evaluated over 24 hours, and 30 ppb evaluated over an entire year, codified at 40 CFR 50.4, remain applicable.<sup>3</sup> However, the EPA is not currently designating areas on the basis of either of these two primary standards. Similarly, the secondary standard for SO<sub>2</sub>, set at 500 ppb evaluated over 3 hours, codified at 40 CFR 50.5, has not been revised, and the EPA is also not currently designating areas on the basis of the secondary standard.

### General Approach and Schedule

Section 107(d) of the CAA requires that not later than 1 year after promulgation of a new or revised NAAQS, state governors must submit their recommendations for designations and boundaries to the EPA. Section 107(d) also requires the EPA to provide notification to states no less than 120 days prior to promulgating an initial area designation that is a modification of a state's recommendation. If a state does not submit designation recommendations, the EPA may promulgate the designations that it deems appropriate without prior notification to the state, although it is our intention to provide such notification when possible. If a state or tribe disagrees with the EPA's intended designations, it is given an opportunity within the 120-day period to demonstrate why any proposed modification is inappropriate. The EPA is required to complete designations within 2 years after promulgation of a new or revised NAAQS, unless the EPA

---

Unit 3 stack to portions of Anne Arundel and Baltimore Counties that are within 26.8 kilometers within Wagner's Unit 3 stack.

<sup>2</sup> The EPA is finalizing our intended area designation of unclassifiable/attainment and the boundary definition consisting of the city's jurisdictional boundary for Baltimore City.

<sup>3</sup> 40 CFR 50.4(e) provides that the two prior primary NAAQS will no longer apply to an area 1 year after its designation under the 2010 NAAQS, except that for areas designated nonattainment under the prior NAAQS as of August 22, 2010, and areas not meeting the requirements of a SIP Call under the prior NAAQS, the prior NAAQS will apply until that area submits and the EPA approves a SIP providing for attainment of the 2010 NAAQS. There are no areas in Maryland subject to this clause.

determines that sufficient information is not available, in which case the deadline is extended to 3 years. The 3-year deadline for the revised SO<sub>2</sub> NAAQS was June 2, 2013.

On August 5, 2013, the EPA published a final rule establishing air quality designations for 29 areas in the United States for the 2010 SO<sub>2</sub> NAAQS, based on recorded air quality monitoring data from 2009 - 2011 showing violations of the NAAQS (78 FR 47191). In that rulemaking, the EPA committed to address, in separate future actions, the designations for all other areas for which the Agency was not yet prepared to issue designations.

Following the initial August 5, 2013 designations, three lawsuits were filed against the EPA in different U.S. District Courts, alleging the Agency had failed to perform a nondiscretionary duty under the CAA by not designating all portions of the country by the June 2, 2013 deadline. In an effort intended to resolve the litigation in one of those cases, plaintiffs Sierra Club and the Natural Resources Defense Council and the EPA filed a proposed consent decree with the U.S. District Court for the Northern District of California. On March 2, 2015, the court entered the consent decree and issued an enforceable order for the EPA to complete the area designations according to the court-ordered schedule.

According to the court-ordered schedule, the EPA must complete the remaining designations by three specific deadlines. By no later than July 2, 2016 (16 months from the court's order), the EPA must designate two groups of areas: (1) areas that have newly monitored violations of the 2010 SO<sub>2</sub> NAAQS, and (2) areas that contain any stationary sources that had not been announced as of March 2, 2015, for retirement and that, according to the EPA's Air Markets Database, emitted in 2012 either (i) more than 16,000 tons of SO<sub>2</sub>, or (ii) more than 2,600 tons of SO<sub>2</sub> with an annual average emission rate of at least 0.45 pounds of SO<sub>2</sub> per one million British thermal units (lbs SO<sub>2</sub>/MmBTU). Specifically, a stationary source with a coal-fired unit that, as of January 1, 2010, had a capacity of over 5 megawatts and otherwise meets the emissions criteria, is excluded from the July 2, 2016, deadline if it had announced through a company public announcement, public utilities commission filing, consent decree, public legal settlement, final state or federal permit filing, or other similar means of communication, by March 2, 2015, that it will cease burning coal at that unit.

The last two deadlines for completing remaining designations are December 31, 2017, and December 31, 2020. The EPA has separately promulgated requirements for state and other air agencies to provide additional monitoring or modeling information on a timetable consistent with these designation deadlines. We expect this information to become available in time to help inform these subsequent designations. These requirements were promulgated on August 21, 2015 (80 FR 51052), in a rule known as the SO<sub>2</sub> Data Requirements Rule (DRR).

Updated designations guidance was issued by the EPA through a March 20, 2015, memorandum from Stephen D. Page, Director, U.S. EPA, Office of Air Quality Planning and Standards, to Air Division Directors, U.S. EPA Regions 1-10. This memorandum supersedes earlier designation guidance for the 2010 SO<sub>2</sub> NAAQS, issued on March 24, 2011, and it identifies factors that the EPA intends to evaluate in determining whether areas are in violation of the 2010 SO<sub>2</sub> NAAQS. The guidance also contains the factors the EPA intends to evaluate in determining the boundaries for all remaining areas in the country, consistent with the court's order and schedule. These

factors include: 1) Air quality characterization via ambient monitoring or dispersion modeling results; 2) Emissions-related data; 3) Meteorology; 4) Geography and topography; and 5) Jurisdictional boundaries. This guidance was supplemented by two non-binding technical assistance documents intended to assist states and other interested parties in their efforts to characterize air quality through air dispersion modeling or ambient air quality monitoring for sources that emit SO<sub>2</sub>. Notably, the EPA's documents titled, "SO<sub>2</sub> NAAQS Designations Modeling Technical Assistance Document" (Modeling TAD) and "SO<sub>2</sub> NAAQS Designations Source-Oriented Monitoring Technical Assistance Document" (Monitoring TAD), were made available to states and other interested parties. Both of these TADs were most recently updated in February 2016.

Based on complete, quality assured and certified ambient air quality data collected between 2013 and 2015, no violations of the 2010 SO<sub>2</sub> NAAQS have been recorded at ambient air quality monitors in any undesignated part of Maryland. However, there one source in the state meeting the emissions criteria of the consent decree for which the EPA must complete designations by July 2, 2016. In this final technical support document (TSD), the EPA discusses its review and technical analysis of Maryland's April 19, 2016 submission for the area that we must designate. The EPA also discusses any final modifications from the state's recommendation based on all available data before us.

The following are definitions of important terms used in this document:

- 1) 2010 SO<sub>2</sub> NAAQS – the primary NAAQS for SO<sub>2</sub> promulgated in 2010. This NAAQS is 75 ppb, based on the 3-year average of the 99th percentile of the annual distribution of daily maximum 1-hour average concentrations. See 40 CFR 50.17.
- 2) Attaining monitor – an ambient air monitor meeting all methods, quality assurance, and siting criteria and requirements whose valid design value is less than or equal to 75 ppb, based on data analysis conducted in accordance with Appendix T of 40 CFR part 50.
- 3) Design Value – a statistic computed according to the data handling procedures of the NAAQS (in 40 CFR part 50 Appendix T) that, by comparison to the level of the NAAQS, indicates whether the area is violating the NAAQS.
- 4) Designated nonattainment area – an area which the EPA has determined has violated the 2010 SO<sub>2</sub> NAAQS or contributed to a violation in a nearby area. A nonattainment designation reflects considerations of the state's recommendations and all of the information discussed in this document. The EPA's decision is based on all available information including the most recent 3 years of air quality monitoring data, available modeling analyses, and any other relevant information.
- 5) Designated unclassifiable area – an area for which the EPA cannot determine based on all available information whether or not it meets the 2010 SO<sub>2</sub> NAAQS.
- 6) Designated unclassifiable/attainment area – an area which the EPA has determined to have sufficient evidence to find either is attaining or is likely to be attaining the NAAQS. The EPA's decision is based on all available information including the most recent 3 years of air quality monitoring data, available modeling analyses, and any other relevant information.
- 7) Modeled violation – a violation based on air dispersion modeling.

- 8) Recommended attainment area – an area a state or tribe has recommended that the EPA designate as attainment.
- 9) Recommended nonattainment area – an area a state or tribe has recommended that the EPA designate as nonattainment.
- 10) Recommended unclassifiable area – an area a state or tribe has recommended that the EPA designate as unclassifiable.
- 11) Recommended unclassifiable/attainment area – an area a state or tribe has recommended that the EPA designate as unclassifiable/attainment.
- 12) Violating monitor – an ambient air monitor meeting all methods, quality assurance, and siting criteria and requirements whose valid design value exceeds 75 ppb, based on data analysis conducted in accordance with Appendix T of 40 CFR part 50.

## **Technical Analysis for the Anne Arundel County and Baltimore County, Maryland Nonattainment Area**

### **Introduction**

The Anne Arundel County and Baltimore County, Maryland, area contains a stationary source that, according to the EPA's Air Markets Database, emitted in 2012 either more than 16,000 tons of SO<sub>2</sub> or more than 2,600 tons of SO<sub>2</sub> and had an annual average emission rate of at least 0.45 pounds of SO<sub>2</sub> per one million British thermal units (lbs SO<sub>2</sub>/mmBTU). Specifically, in 2012, the Herbert A. Wagner Generating Station (Wagner, or the Facility), emitted 7,514 tons of SO<sub>2</sub> and had an emissions rate of 1.105 lbs SO<sub>2</sub>/mmBTU. As of March 2, 2015, this stationary source had not met the criteria for being "announced for retirement." Pursuant to the March 2, 2015, court-ordered schedule, the EPA must designate the area surrounding this facility by July 2, 2016.

In its April 19, 2011, submission to the EPA for designations for the 2010 SO<sub>2</sub> NAAQS, Maryland recommended that an area that includes Wagner, specifically the entirety of Anne Arundel County, be designated as unclassifiable. The 2011 submission, however, did not include any supporting analyses. Subsequently, in its November 20, 2015, updated designation recommendation submission to the EPA, Maryland recommended that the area surrounding Wagner be designated as attainment. Maryland, however, did not recommend any particular boundary for the area in its November 20, 2015, submission. Maryland also stated that no monitors in Maryland violated the 1-hour SO<sub>2</sub> NAAQS, and the EPA has confirmed this. On January 15, 2016, Maryland submitted a supplement to its 2015 recommendation which included a modeling analysis for the area around Wagner. Additionally, this supplement included State comments on the air dispersion modeling dated January 4, 2016, submitted to the EPA by Sierra Club, asserting that violations of the NAAQS are present in the area around Wagner. After review of the Sierra Club modeling, the EPA agreed with the Sierra Club modeling and proposed to designate portions of Anne Arundel and Baltimore Counties as nonattainment for the SO<sub>2</sub> standard. Additionally, the EPA proposed to designate Baltimore City as unclassifiable/attainment based on the Sierra Club modeling.

On February 16, 2016, the EPA notified Maryland that we intended to designate the Anne Arundel County and Baltimore County, Maryland area as nonattainment, based on our view that the area was not meeting the NAAQS. Additionally, we informed Maryland that our intended boundary for the nonattainment area consisted of portions of Anne Arundel and Baltimore Counties that are within 35.5 kilometers of Herbert A. Wagner's Unit 3 stack, which is located at 39.17765N latitude, 76.52752W longitude. Our intended designation and associated boundaries were based on air dispersion modeling submitted by Sierra Club that was used in lieu of actual monitored data in order to designate the area. It provided evidence that 2010 SO<sub>2</sub> NAAQS violations are occurring within Baltimore County and Anne Arundel County. Furthermore, our intended designation and associated boundaries were also based on the EPA's analysis of emissions data, the lack of federally enforceable SO<sub>2</sub> emission controls at Wagner, and general wind patterns and topography. The EPA noted that Maryland's modeling analysis was not conducted in accordance with the EPA's Modeling TAD or Appendix W, and did not support a finding that the area was meeting the NAAQS and an attainment designation. Detailed rationale, analyses, and other information supporting our intended designation for this area can be found in the TSD for our intended designation in Maryland, and that document along with all others related to this rulemaking can be found in Docket ID EPA-HQ-OAR-2014-0464.

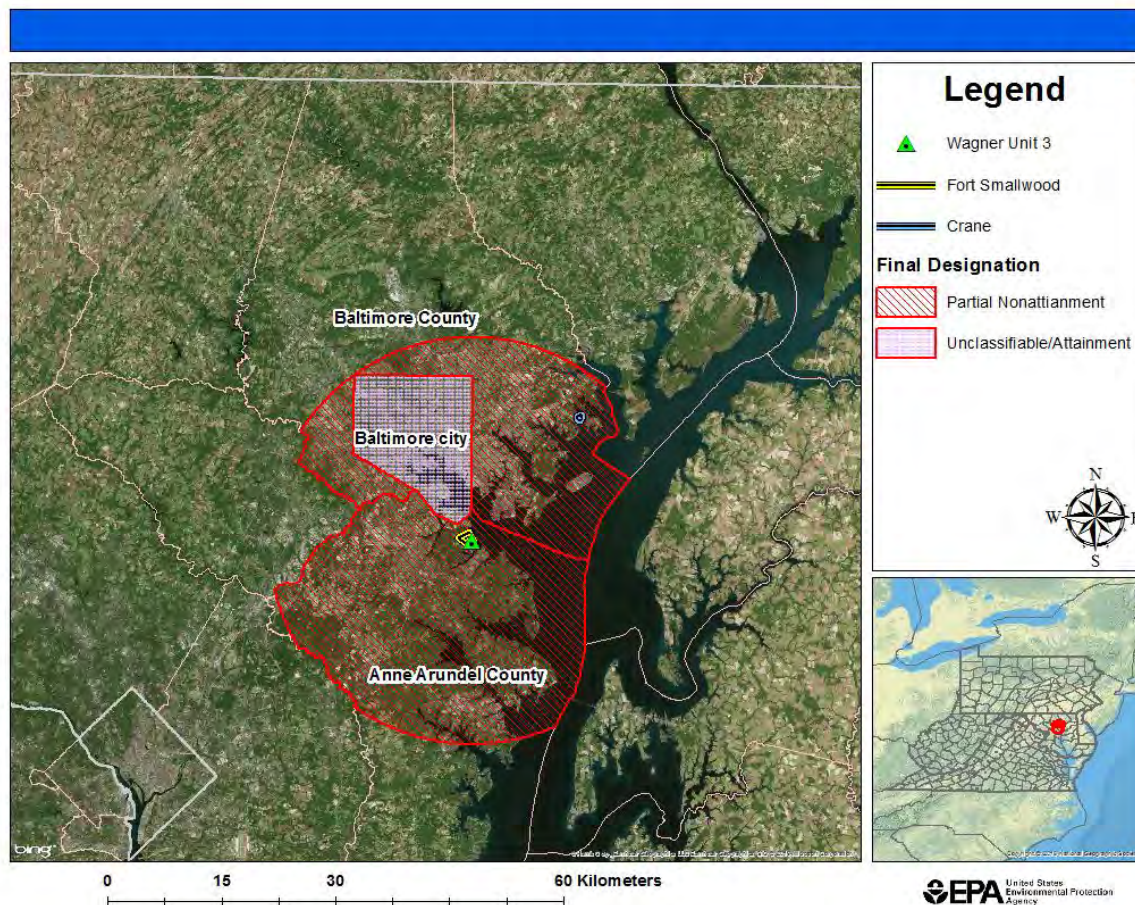

#### Assessment of New Information

In our February 16, 2016, notification to Maryland regarding our intended nonattainment designation for the Anne Arundel County and Baltimore County, Maryland, area, the EPA requested that any additional information that the Agency should consider prior to finalizing the designation should be submitted by April 19, 2016. On March 1, 2016, the EPA also published a notice of availability and public comment period in the *Federal Register*, inviting the public to review and provide input on our intended designations by March 31, 2016 (81 FR 10563).

The EPA is explicitly incorporating and relying upon the analyses and information presented in the TSD for our intended designation for the purposes of our final designation for this area, except to the extent that any new information submitted to the EPA or conclusions presented in this TSD for our final designation and our response to comments document (RTC), available in the docket, supersede those found in the preliminary technical support document.

As further detailed below, after carefully considering all available data and information, the EPA is designating the Anne Arundel County and Baltimore County, Maryland, area as nonattainment for the 2010 SO<sub>2</sub> NAAQS, but we are designating a smaller nonattainment area than we had identified in our February 16, 2016, notification. The boundaries for this nonattainment area consist of portions of Anne Arundel and Baltimore Counties that are within 26.8 kilometers of Herbert A. Wagner's Unit 3 stack, which is located at 39.17765N latitude, 76.52752W longitude, and are shown in the figure below. Also included in the figure are nearby emitters of SO<sub>2</sub>. Additionally, as shown in the figure below and further detailed later in this document, the EPA is designating Baltimore City as unclassifiable/attainment.

**Figure 1. EPA's Final Anne Arundel County and Baltimore County, Maryland Nonattainment Area**

The EPA received substantive comments regarding our intended nonattainment designation for the Anne Arundel County and Baltimore County, Maryland area from citizens, citizen groups, Sierra Club, industry, and Maryland. Our responses to those comments are provided in the response to comments document (RTC), available in the docket.

Also, additional air dispersion modeling was submitted to the EPA during the state and public comment period in order to characterize air quality in the Anne Arundel County and Baltimore County, Maryland, area. Notably, Sierra Club provided additional air dispersion modeling information during the comment period asserting that the EPA should finalize the proposed nonattainment designation for the area surrounding Wagner. Additionally, Maryland submitted additional air dispersion modeling asserting that the EPA should designate the area surrounding Wagner as attainment, as a first option, or unclassifiable, as a second option, in the face of conflicting modeling analyses. Maryland also stated that if the EPA disagrees with Maryland's recommended designation and designates the area as nonattainment, the nonattainment area should be much smaller with a boundary description comprised of roads and a land/water

interface. This information was submitted by Maryland to support a modification to both our proposed designation and our proposed designation boundary for the area. The EPA disagrees with Maryland's recommendations of attainment and unclassifiable, as modeling analyses submitted by both Sierra Club and Maryland, that were conducted in accordance with the TAD and Appendix W, show violations in the area surrounding Wagner. Based on new information received during the comment period, the EPA agrees that the nonattainment area should be smaller; however, based on analyses of the 5 factors and a modeled contribution analysis, the EPA disagrees that the area should be comprised of the roads and land/water interface that Maryland suggested. Similarly to what was proposed, the EPA is finalizing a nonattainment area using a radius drawn from Wagner's unit 3 stack. The nonattainment area, however, is being reduced to a shorter radius drawn from Wagner's unit 3 stack, but is still inclusive of all modeled violations close in proximity to Wagner as well as sources the EPA has determined to be contributing to these modeled violations. The discussion and analysis of this new information that follow reference the Modeling TAD, Monitoring TAD, and the factors for evaluation contained in EPA's March 20, 2015, guidance, as appropriate and applicable.

## Detailed Assessment of Sierra Club's and the State of Maryland's New Modeling

### *Summary of Recent Air-Dispersion Model Submissions*

The EPA received multiple modeling analyses from Sierra Club and the State of Maryland. Sierra Club submitted four (4) AERMOD simulations for all coal-fired units at Brandon Shores, C.P Crane and Wagner, six (6) units overall. The State of Maryland submitted five (5) AERMOD simulations for the same units Sierra Club modeled but added two (2) oil units at Wagner and the Wheelabrator Baltimore Incinerator for a total of nine (9) units. Table 2 lists the modeling analyses that were considered in our final designation decision. Our final designations are based on modeling submitted by the State of Maryland (BETA Adjust U\* modeling showing nonattainment submitted by Maryland and referred to as the Appendix D Modeling Analysis), though we determined a smaller boundary was appropriate than the State recommended with this modeling. The EPA finds that this modeling analysis is the most accurate as it best follows the modeling TAD and March 20, 2015 guidance, and in our technical judgement, appears most representative of actual air quality in the area surrounding Wagner.

**Table 2. Summary of Model Analyses Considered for Final Designation**

Submittal Package	Reference Document	Source Description	Mode	Period Modeled
Sierra Club	Appendix B Exhibit 3	Hourly Emissions/Fixed Stack Rates	Regulatory Default	2012-14
Sierra Club	Appendix B Exhibit 3	Hourly Emissions/Variable Stack Rates	Regulatory Default	2012-14
Sierra Club	Appendix B Exhibit 3	Hourly Emissions/Fixed Stack Rates	Regulatory Default	2013-15
Sierra Club	Appendix B Exhibit 3	Hourly Emissions/Variable Stack Rates	Regulatory Default	2013-15
State of Maryland	Appendix A	Hourly Emissions/Variable Stack Rates	Non-Default <sup>1</sup>	1 Apr 2015 - 31 Mar 2016
State of Maryland	Appendix A	Hourly Emissions/Variable Stack Rates	Non-Default <sup>2</sup>	1 Apr 2015 - 31 Mar 2016
State of Maryland	Appendix C	Hourly Emissions/Variable Stack Rates	Regulatory Default	2013-15

**Regulatory Default, AERMOD version 15181 regulatory default mode**

<sup>1</sup> AERMOIST, nondefault plume enhancement technique

<sup>2</sup> AERMOIST, nondefault plume enhancement technique; Adjust U\* and LOWWIND 3 AERMOD BETA Options

<sup>3</sup> Adjust U\* AERMOD BETA Option. Approval sought and granted through June 20, 2016 Concurrence with Model Clearinghouse under Section 3.2 of Appendix W

### *Sierra Club Modeling Summary*

Sierra Club submitted modeling as part of comments submitted during the 30-day public comment period that closed on March 31, 2016. This modeling<sup>4</sup> was essentially an update of Sierra Club's previous submittal and included more recent hourly emissions data (2013-15), hourly varying stack flow rates, and updated background concentrations.

A total of four (4) AERMOD simulations were presented. Sierra Club modeled six (6) sources at allowable and actual hourly emission rates. Only the actual hourly emission rate runs were reviewed by the EPA since this is the recommended method outlined in the EPA's Modeling TAD. The modeled hourly emission rates were nearly identical to those pulled from the EPA's Clean Air Markets website.<sup>5</sup> Two (2) three-year periods were modeled: 2012-14 and 2013-15. Stack parameters for each three-year period were either set to fixed temperatures and flow rates for each modeled unit or used the same fixed temperature along with hourly varying flow rates derived from 2012-14 CEM data made available by the EPA. Background concentrations increased slightly (26.2 µg/m<sup>3</sup> versus 28.8 µg/m<sup>3</sup>) reflecting a slight increase in the background monitor's most recent 3-year design value. The model receptor grid was identical to Sierra Club's previous submittal and was comprised of a 50km by 50km domain centered on the Brandon Shores/Crane/Wagner power plants and included over 97,000 individual (1.5 m flagpole) receptors. Meteorological data from the Baltimore/Washington International (BWI) and Dulles airports was processed in AERMET with supplemental 5-minute and 2-minute surface wind data using EPA's AERMINUTE program. Surface characteristics were processed seasonally with continuous winter season snow cover using AERSURFACE.

Sierra Club's updated modeling continued to show modeled violations surrounding Wagner with additional areas of violating receptors in portions of Baltimore County west and north of the City of Baltimore. Comparisons of the "fixed" and "variable" stack rate runs show that AERMOD concentrations are sensitive to stack flow rates. In general, the runs using the "fixed" stack rates yielded higher concentrations than the runs with "variable" stack rates.

The EPA is not relying upon Sierra Club's most recent modeling for designation purposes. The simulations generally followed EPA's Modeling TAD but produced modeled violations in areas of Baltimore County greater than 20 km from Wagner that seem questionable in reflecting this area's actual air quality based on the EPA's technical knowledge and judgment. Modeling completed by the State of Maryland using the same default version of AERMOD as Sierra Club produced modeled violations even farther away from Wagner than those modeled in Sierra Club's. Maryland extended the modeling domain outward from Sierra Club's to ensure all modeled violations were captured. The State of Maryland examined these new areas of modeled violations and noted they occurred during the overnight hours under stable atmospheric conditions with low wind speeds. The EPA developed and included the BETA Adjust U\* option

---

<sup>4</sup> Sierra Club modeling described in report entitled *C.P. Crane Generating Station Chase, Maryland Brandon Shores & H.A. Wagner Generating Stations Fort Smallwood Complex, Maryland Evaluation of Compliance with the 1-hour NAAQS for SO<sub>2</sub>* dated March 23, 2016, from Wingra Engineering, S.C. Madison, Wisconsin.

<sup>5</sup> <https://ampd.epa.gov/ampd/>

within AERMOD (starting with version 12345) to address concerns with simulating concentrations under these conditions. A more thorough discussion of this can be found in the next section discussing the State of Maryland's modeling submission (specifically Appendix C modeling).

Commenter (0332-AB-Sierra Club) stated that, while Sierra Club believes that their 2015 modeling fully supports a nonattainment designation, they attached a supplemental modeling report (Appendix B Exhibit 3) demonstrating that the results of the 2015 modeling report are robust to the modeling years selected, the use of emission data from the EPA's Emissions Modeling Clearinghouse and to the inclusion of variable hourly exit velocities. Commenter stated that, consistent with these conclusions and with the supplemental information described in their letter and attachments, they urged the EPA to finalize its proposed nonattainment designation for the areas around the Wagner coal-fired power plant.

### *State of Maryland Modeling Summary*

The State of Maryland submitted several sets of modeling analyses during their 60-day state response period, which ended April 19, 2016. Maryland's preferred recommendation for the Wagner area is attainment. Updated modeling was included in Appendix A, Appendix C, and Appendix D of their submittal. Each of these appendices will be briefly discussed in the following sections. The EPA believes that the modeling presented in Appendix D of Maryland's submittal best followed EPA's Modeling TAD and associated guidance and is the most likely to reflect actual air quality conditions in the Wagner area.

### *State of Maryland Appendix A Modeling Summary*

Modeling submitted as part of Maryland's Appendix A was presented to support its preferred designation of attainment for the Wagner area. The modeling analyses in Appendix A were developed by Wagner's consultant and were an attempt to simulate conditions for a low-sulfur coal switch that recently took place for Wagner Unit 2 in response to the EPA's Mercury Air Toxics Standards (MATS). Two sets of modeling were presented with both simulations resulting in model concentrations below the 1-hour SO<sub>2</sub> NAAQS.

Both model simulations in Appendix A included one year of meteorological data developed with surface and upper air soundings from BWI and Dulles Airport respectively. This period extended from April 1, 2015, through March 31, 2016, and covered the period in which the fuel switch for MATS occurred at Wagner's Unit 2 coal-fired boiler.<sup>6</sup> Meteorological data was processed with supplemental 2-minute wind information from BWI using AERMINUTE and included monthly varying surface characteristics with no seasonal snow cover. The modeling domains covered the same area used by Sierra Club with an extension at the edge of the northwest corner to ensure the peak concentrations were captured. There were a little over 10,000 individual model receptors in Maryland's receptor grid. Receptors were excluded from areas where monitors could not be

---

<sup>6</sup> This unit is currently on PJM's Future Deactivation List. Its listed shutdown date is June 1, 2020. See: <http://www.pjm.com/planning/generation-deactivation/gd-summaries.aspx>.

sited, specifically over water bodies, as allowed in the EPA's Modeling TAD. Company-provided hourly CEM emission rates and stack parameters including both stack temperatures and stack flow rates were used. EPA finds that these actual rates are more accurate than information used in Sierra Club's "varying" stack rate simulations.

While both one-year simulations showed compliance with the 1-hour SO<sub>2</sub> NAAQS, the EPA finds that there were several deficiencies present that led us to conclude that these results do not support Maryland's preferred attainment designation for the Wagner Area. Appendix A model runs were split into a "default" AERMOD run and a non-default run. The EPA is providing the following comments to explain why these modeling runs are not appropriate for consideration in its final designation for the Wagner area.

**AERMOIST creates an aberration that precludes this analysis from being considered Regulatory Default:** AERMOIST is a plume enhancement technique that attempts to account for the impacts of moisture-laden plumes from Brandon Shore's Flue-Gas Desulfurization (FGD) units on final model plume rise. AERMOIST calculates latent heating in these moist plumes and then adjusts stack temperatures (upward). This is accomplished by feeding adjusted stack temperatures back into AERMOD through the hourly emission file. The EPA has thus far not determined the regulatory status of AERMOIST, so we currently cannot accept this component as part of the EPA's regulatory default AERMOD package.

Furthermore, an analysis of the output files shows that the Brandon Shore units were emitting during the hour which defined the simulation's 1-hr SO<sub>2</sub> design value (the 99<sup>th</sup> %). Based on the EPA's knowledge of AERMOIST and analysis that this simulation's design value was 99.93% of the NAAQS and the Brandon Shore units were emitting at that time, it's very likely that AERMOIST contributed to the simulation showing compliance with the NAAQS. In other words, without AERMOIST this simulation would have most likely exceeded the NAAQS.

**Use of only one year of met data is not necessarily reflective of the Wagner area's modeled design value.** The EPA recognizes Maryland's attempt to project what current operations at Wagner would be given the facility's recent switch to lower sulfur coal in Unit 2. The EPA notes, however, that this coal switch was not federally enforceable. In addition, using only one year of simulation time would not accurately reflect what the area's design value would be, which is the purpose of the modeling analysis. A more accurate representation would have included three years of met data as outlined in EPA's Modeling TAD. Furthermore, given the closeness to the standard of Maryland's "default" run and the impact of the currently unapproved use of AERMOIST, it is highly likely that if Maryland had run the most recent three years of meteorological and emissions that the model results would have exceeded the 1-hour SO<sub>2</sub> NAAQS.

**Maryland's non-default run included in Appendix A uses options that were not approved under Section 3.2.2 of Appendix W.** The non-default run presented in Appendix A showed model concentrations in the Wagner area that were below the NAAQS. This run, however, utilized several BETA options within AERMOD that would

need approval under Section 3.2.2 of Appendix W. These included the BETA Adjust U\* and Low Wind 3 options within AERMOD along with the previously mentioned AERMOIST component. No formal approval request was sought or given for these two BETA options, which is contrary to the EPA's December 10, 2015 Clearinghouse Memorandum,<sup>7</sup> meaning that it would not be appropriate for the EPA to rely upon the results from this run for the purpose of designating the area around the Wagner facility.

#### *State of Maryland Appendix C Modeling Summary*

Two (2) AERMOD simulations, showing nonattainment, were included as part of Appendix C. This included a default AERMOD run and a run using EPA's BETA Adjust U\* option. These runs were submitted as part of an official request to use an alternative model under Section 3.2.2 of Appendix W. This request was outlined in Maryland's April 14, 2016, letter to the EPA Region 3 Regional Administrator. After an internal technical review, a short summary was developed and a formal concurrence request was submitted to the EPA's Model Clearinghouse on May 13, 2016. The Model Clearinghouse granted approval of Maryland's request on June 20, 2016, and the approval memorandum is available in the docket under this rulemaking.

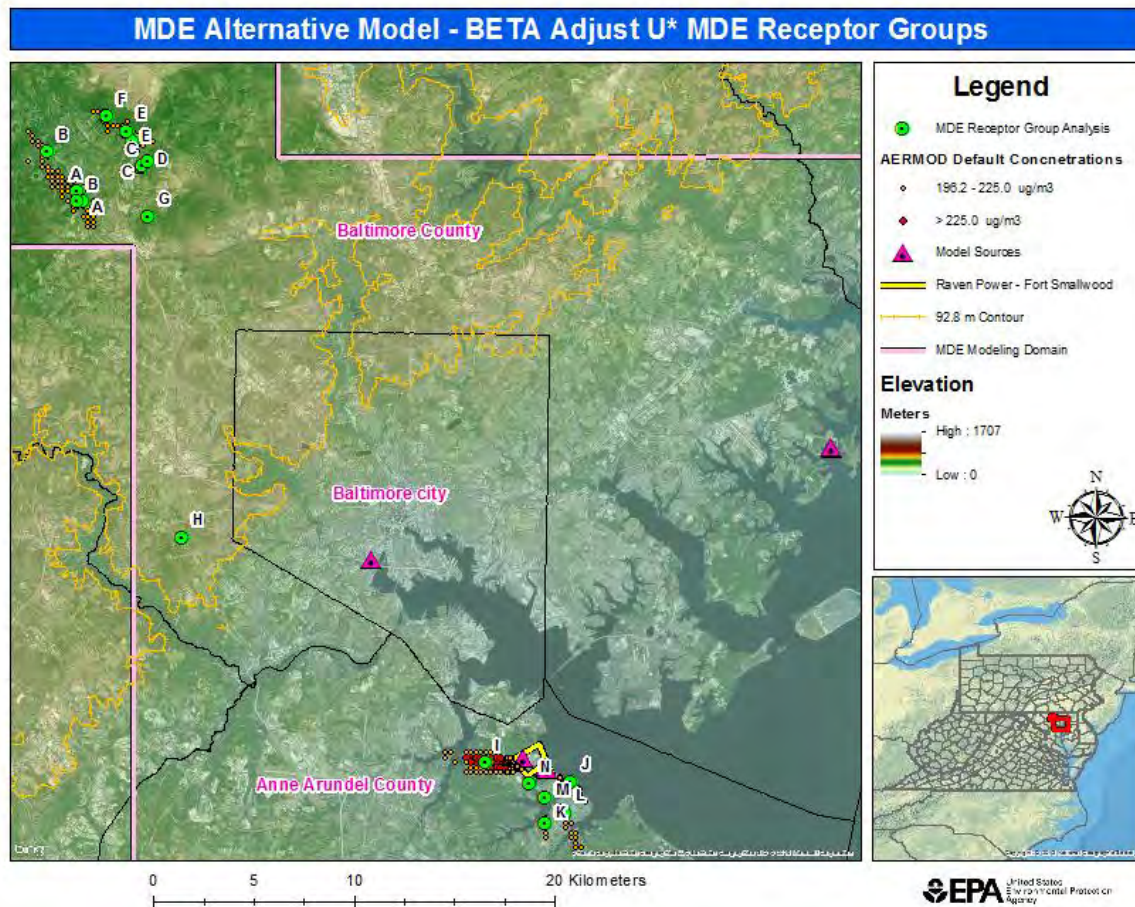

Maryland's default AERMOD run showed similar areas of modeled violations as Sierra Club's model simulations. Violations were clustered in the immediate area of the Wagner power plant as well as several areas in Baltimore County to the west and north of the City of Baltimore. Model violations extended out to almost 40 km from Wagner. Both AERMOD runs used three (3) years of surface and upper air soundings from BWI and Dulles airports for the 2013-2015 time period. Surface winds were supplemented with 2-minute surface wind data processed in AERMET using monthly varying surface characteristics including soil moisture with no seasonal snow cover via AERSURFACE. Hourly emissions, stack temperature, and flow rates were used for all units at Brandon Shores, C.P. Crane, and Wagner. Emission rates and stack parameters were held constant for the Wheelabrator Baltimore Incinerator.

Figure 2 shows the locations of the receptors in Maryland's default AERMOD run that exceeded the 1-hour SO<sub>2</sub> NAAQS in the extended Wagner area. This figure was included in the EPA's May 13, 2016 technical analysis that was sent the Model Clearinghouse for concurrence. Violating receptors can be generally broken into two (2) groups. Far away receptors (A-H) that occur in the elevated Piedmont terrain and close-in receptors (I-N) that reside on the Atlantic Coastal Plane. The 92.8m contour marks effective stack height for Wagner Unit 3.

#### **Figure 2. AERMOD Default run violating receptors from Maryland's Appendix C run**

---

<sup>7</sup> [https://www3.epa.gov/ttn/scram/guidance/clarification/AERMOD\\_Beta\\_Options\\_Memo-20151210.pdf](https://www3.epa.gov/ttn/scram/guidance/clarification/AERMOD_Beta_Options_Memo-20151210.pdf)

Maryland examined the dates and times for several representative receptors (labeled A through N in Figure 2) from the group of violating receptors in its default AERMOD run. Receptors A through H had peak model concentrations occurring during the overnight hours under low wind speeds. Violating receptors near Wagner (receptors I through N) occurred during daytime hours with modestly higher wind speeds. Table 3 shows the dates and times for these representative violating receptors along with the hourly wind speed and  $U^*$  values from the simulation's AERMET surface file. There are two sets of columns: one for the default AERMET run and one using the BETA Adjust  $U^*$  run. The BETA  $U^*$  values for receptors A through H increased while values for I through M did not change (there was a slight increase for receptor N). As explained earlier, EPA's BETA Adjust  $U^*$  increases the  $U^*$  value only in instances of stable (including overnight), low-wind speed conditions.

The EPA received comments from Sierra Club objecting to the modeling provided by AECOM to Maryland because the EPA has not formally approved the use of the ADJ\_  $U^*$  and LOWWIND3 options as the regulatory default under Appendix W and because AECOM failed to support the preferability of these options for modeling the Baltimore-area coal plants, especially for determining whether the area is attaining the 1-hour  $SO_2$  NAAQS. Commenter provided discussion of this issue in their letter and attachments, including attached comments of

Camille Sears (Exhibit 4). Also see discussion of these options in section III.A.1 of this document.

**Table 3. Change in representative violating receptor U\* values using AERMET in default and BETA Adjust U\* modes**

Group	X	Y	Elevation (m)	Year	Julian Day	Hour	Default AERMET		BETA Adjust U*	
							Surface Friction Velocity (u*) (m/s)	Wind Speed	Surface Friction Velocity (u*) (m/s)	Wind Speed

Running the BETA Adjust U\* option in AERMOD does not eliminate all violating receptors in Maryland's Appendix C runs. Model violations in close proximity (within 6 km) to Wagner continue to occur even with the BETA Adjust U\* option. The BETA Adjust U\* option appears to reduce the concentration peaks occurring in Baltimore County west and north of the City (i.e., the 'far away' receptors) of Baltimore such that there are no longer violating receptors in that area. These default AERMOD run violations are probably occurring due to AERMOD potentially over predicting concentrations during times of low wind/stable conditions. The EPA finds that the specified use of BETA Adjust U\* in the latter Appendix C run provides a more realistic estimate of actual conditions in Anne Arundel County, Baltimore County, and the City of Baltimore surrounding the Wagner power plant.

#### *State of Maryland Appendix D Modeling Summary*

Modeling presented in Maryland's Appendix D is identical to the BETA Adjust U\* run included in Appendix C. Maryland presented the results of this run to provide a possible alternative to their preferred Attainment designation for the Wagner area. Model results showed violating receptors were confined to areas within 6 km of Wagner. If the Appendix A model simulations were not acceptable, as the EPA has now determined that they are not, Maryland proposed defining a nonattainment area based on several road segments that enclosed the violating receptors.

### *Model Selection and Modeling Components for Modeling Used in Designation Decision*

The EPA's Modeling TAD notes that for area designations under the 2010 SO<sub>2</sub> NAAQS, the AERMOD modeling system should be used, unless use of an alternative model can be justified. In some instances the recommended model may be a model other than AERMOD, such as the BLP model for buoyant line sources. The AERMOD modeling system contains the following components:

- AERMOD: the dispersion model
- AERMAP: the terrain processor for AERMOD
- AERMET: the meteorological data processor for AERMOD
- BPIPPRIME: the building input processor
- AERMINUTE: a pre-processor to AERMET incorporating 1-minute automated surface observation system (ASOS) wind data
- AERSURFACE: the surface characteristics processor for AERMET
- AERSCREEN: a screening version of AERMOD

After reviewing modeling multiple analyses sent by Sierra Club and the State of Maryland, the EPA finds that the BETA Adjust U\* AERMOD simulation included in Maryland's Appendix D most closely follows the Modeling TAD and the EPA's March 20, 2015, guidance and therefore more accurately represents true air quality in the Wagner area. As currently required, Maryland formally requested the use of the BETA Adjust U\* option in AERMOD under Section 3.2.2 of Appendix W. After a concurrent technical review by Region 3 and the Model Clearinghouse, the EPA has provided a formal approval to use the BETA Adjust U\* option within AERMOD. Concurrence was granted by the Model Clearinghouse on June 20, 2016 and it is available in the docket under this rulemaking.

Modeling used in Maryland's Appendix D was completed using a version of Lakes Environmental software that includes AERMOD's most recent version (15181). As noted previously, AERMOD was run using the non-default BETA Adjust U\* option. As noted in EPA's *Addendum Users Guide for the AERMOD Meteorological Preprocessor (AERMET)* ... "[T]he ADJ\_U\* "BETA" option is considered to be a non-Default option and is therefore subject to the alternative model provisions in Section 3.2 of Appendix W (40 CFR Part 51)."

### *Modeling Parameter: Rural or Urban Dispersion*

The EPA's recommended procedure for characterizing an area by prevalent land use is based on evaluating the dispersion environment within 3 km of the facility. According to the EPA's modeling guidelines contained in documents such as the Modeling TAD, rural dispersion coefficients are to be used in the dispersion modeling analysis if more than 50% of the area within a 3 km radius of the facility is classified as rural. Conversely, if more than 50% of the area is urban, urban dispersion coefficients should be used in the modeling analysis. When performing the modeling for the area of analysis, Maryland determined that it was most appropriate to run the model using rural dispersion coefficients. Upon review of land use

surrounding the Wagner power plant, the EPA determined that Maryland's use of rural dispersion coefficients was appropriate in this model run.

*Modeling Parameter: Area of Analysis (Receptor Grid)*

The EPA believes that a reasonable first step towards characterization of air quality in the area surrounding the Wagner power plant is to determine the extent of the area of analysis, i.e., receptor grid. Considerations presented in the Modeling TAD include but are not limited to: the location of the SO<sub>2</sub> emission sources or facilities considered for modeling; the extent of significant concentration gradients of nearby sources; and sufficient receptor coverage and density to adequately capture and resolve the model predicted maximum SO<sub>2</sub> concentrations.

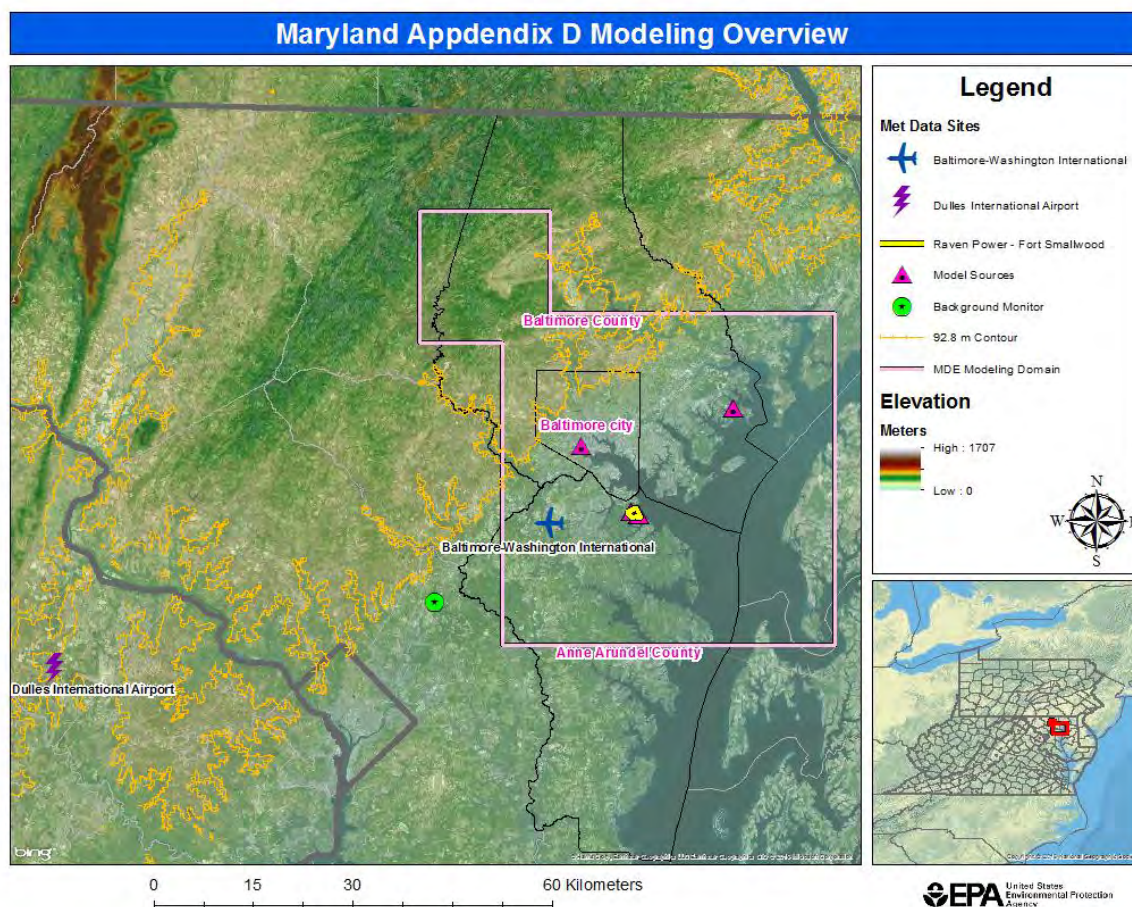

The grid receptor spacing for the area of analysis chosen by Maryland is as follows:

- 25 meter spacing along the Fort Smallwood ambient boundary (Brandon Shores/Wagner)
- Irregular spacing along ambient boundary for C.P. Crane
- 100m spacing within the first 4 km from Fort Smallwood and C.P. Crane
- 250m spacing from 4 km to 10 km from Fort Smallwood and C.P. Crane
- 500m spacing for the remainder of domain outside of 10 km from Fort Smallwood and C.P. Crane
- 250m spacing for the 20 km by 20 km grid added onto northwest corner of Sierra Club modeling domain

The receptor network contained 17,000 individual receptors and covered portions of Anne Arundel and Baltimore counties as well as the City of Baltimore. Figure 3 shows the chosen area of analysis surrounding the Wagner power plant, which along with Brandon Shores is part of the Fort Smallwood complex, as well as the domain for the modeling analysis. Consistent with the Modeling TAD, receptors for the purposes of this designation effort were placed only in areas where it would also be feasible to place a monitor and record ambient air impacts. The impacts of the area's geography and topography will be discussed later within this document.

**Figure 3. Overview of Modeling Domain for the Wagner Area of Analysis**

For the area around the Wagner power plant, Maryland included emissions from Brandon Shores, which along with Wagner make up the Fort Smallwood complex, the Wheelabrator Baltimore Incinerator located in the City of Baltimore and C.P. Crane, a two (2) unit coal-fired power plant located in the eastern part of Baltimore County. The Wheelabrator Baltimore Incinerator is located approximately 12.5 km northwest of Wagner, and C.P. Crane is located almost 22 km northeast of Wagner. These facilities represent the largest operating SO<sub>2</sub> sources in the Wagner area. The combination of Maryland's choice of sources to model and the extent and distribution of model receptor points within the modeling domain ensures that the modeling analysis will properly assess source impacts in the Wagner area.

*Modeling Parameter: Source Characterization*

Maryland characterized the sources within the area of analysis in accordance with practices outlined as acceptable in the Modeling TAD. Specifically, Maryland used actual stack heights in conjunction with actual emission rates. Hourly emission rates were used for the Brandon Shores, C.P. Crane, and Wagner based on CEM data for these units. Emission rates for the Wheelabrator Baltimore Incinerator were held constant throughout the model simulation. Buildings at the Fort Smallwood complex (Brandon Shores and Wagner) were included in the modeling analysis, allowing for downwash assessment to be included for the area immediately surrounding the Wagner power plant. This building information was processed using EPA's BPIP-PRIME (version 04274) program. Units at Brandon Shores are vented through a dual-flue stack. The modeling uses merged stack principles<sup>8</sup> when both units are operating simultaneously. In addition to hourly varying emission rates for Brandon Shores, C.P. Crane, and Wagner, stack temperatures and velocity rates varied on an hourly basis based on company provided CEM data.

#### *Modeling Parameter: Emissions*

The EPA's Modeling TAD notes that for the purposes of modeling to characterize air quality for use in designations, the recommended approach is to use the most recent three (3) years of actual emissions data and concurrent meteorological data. However, the TAD also provides for the flexibility of using allowable emissions in the form of the most recently permitted (referred to as PTE or allowable) emissions rate.

The EPA believes that CEMS data provide acceptable historical emissions information when it is available and that these data are available for many electric generating units. In the absence of CEMS data, the EPA's Modeling TAD highly encourages the use of AERMOD's hourly varying emissions keyword HOUREMIS or through the use of AERMOD's variable emissions factors keyword EMISFACT. When choosing one of these methods, the EPA believes that detailed throughput, operating schedules, and emissions information from the impacted sources should be used.

In certain instances, states and other interested parties may find that it is more advantageous or simpler to use PTE rates as part of their modeling runs. Specifically, a facility may have recently adopted a new federally enforceable emissions limit, been subject to a federally enforceable consent decree, or implemented other federally enforceable mechanisms and control technologies to limit SO<sub>2</sub> emissions to a level that indicates compliance with the NAAQS. These new limits or conditions may be used in the application of AERMOD. In these cases, the Modeling TAD notes that the existing SO<sub>2</sub> emissions inventories used for permitting or SIP planning demonstrations should contain the necessary emissions information for designations-related modeling. In the event that these short-term emissions are not readily available, they may be calculated using the methodology in Table 8-1 of Appendix W to 40 CFR Part 51 titled, "Guideline on Air Quality Models."

As previously noted, Maryland included Wagner and three (3) other significant emitters of SO<sub>2</sub> within the City of Baltimore and Baltimore County. These included all of the major combustion units at Brandon Shores, C.P. Crane, and Wagner along with the Wheelabrator Baltimore Incinerator. Maryland believes the modeling domain adequately represents the area where

---

<sup>8</sup> See Section 2.2 of the EPA's *Screening Procedures for Estimating the Air Quality Impact of Stationary Sources*.

maximum concentrations of SO<sub>2</sub> are expected to occur and includes all sources which might contribute to those concentrations. No other sources were determined by Maryland to have the potential to cause significant concentration gradient impacts within the area of analysis. The facilities in the area of analysis and their associated annual actual SO<sub>2</sub> emissions from 2013 to 2015 are summarized in Table 4. The emissions were summed from the hourly emission file used in the modeling analysis to represent hourly varying emissions from units at Brandon Shores, C.P. Crane, and Wagner. Summed emissions and actual hourly emissions were based on CEMS data provided by the operators and were verified using the EPA's Clean Air Markets Division<sup>9</sup> for these three sources. As noted previously, the Wheelabrator Baltimore Incinerator used a constant emission rate over the simulation period.

**Table 4. Actual SO<sub>2</sub> Emissions in 2013-15 from Facilities in Maryland's Area of Analysis**

Facility Name	SO <sub>2</sub> Emissions (tons per year or tpy)		
	2013	2014	2015
Brandon Shores Unit 1	1,389.0	1,669.9	1,310.1
Brandon Shores Unit 2	1,481.3	1,475.2	1,642.5
C.P. Crane Unit 1	831.3	573.4	387.9
C.P. Crane Unit 2	2,140.3	1,313.8	953.9
Wagner Unit 1	0.2	72.6	65.1
Wagner Unit 2	1,568.3	1,946.7	1,185.9
Wagner Unit 3	8,553.5	7,276.1	8,756.6
Wagner Unit 4	72.7	322.5	186.2
Wheelabrator Baltimore Incinerator	438.0	438.0	438.0
Total Emissions From All Facilities in Maryland's Area of Analysis	<b>16,474.6</b>	<b>15,088.2</b>	<b>14,926.2</b>

#### *Modeling Parameter: Meteorology and Surface Characteristics*

The most recent 3 years of meteorological data (concurrent with the most recent 3 years of emissions data) should be used in designations efforts. As noted in the Modeling TAD, the selection of data should be based on spatial and climatological (temporal) representativeness. The representativeness of the data are based on: 1) the proximity of the meteorological monitoring site to the area under consideration, 2) the complexity of terrain, 3) the exposure of the meteorological site, and 4) the period of time during which data are collected. Sources of meteorological data include National Weather Service (NWS) stations, site-specific or onsite data, and other sources such as universities, the Federal Aviation Administration (FAA), and military stations.

For the Wagner area of analysis, surface meteorology from the NWS station at the BWI airport, approximately 12 km west of the Fort Smallwood Complex and coincident upper air

<sup>9</sup> <https://ampd.epa.gov/ampd/>

observations from the NWS station at the Dulles Airport, approximately 91 km to the west-southwest were selected (*see* Figure 3). This data was considered representative of meteorological conditions within the area of analysis.

Maryland used AERSURFACE version 13016 using data from the BWI NWS station south of the City of Baltimore located at 39.1733 N latitude and 76.6841 W longitude to estimate the surface characteristics of the area of analysis. AERSURFACE was run using the standard twelve (12) 30° sectors. Surface characteristics included albedo (the fraction of solar energy reflected from the earth back into space), Bowen ratio (the method generally used to calculate heat lost or heat gained in a substance), and surface roughness (sometimes referred to as “Zo”). These values varied monthly. Bowen ratios were adjusted based on precipitation values to be either wet, dry or average. Surface roughness was calculated based on land use categories from the 1992 USGS land cover database for Maryland out to 1 km from the BWI ASOS tower location.

Meteorological data from the BWI and Dulles Airport surface and upper air stations were used in generating AERMOD-ready files with the AERMET processor. The output meteorological data created by the AERMET processor is suitable for being applied with AERMOD input files for AERMOD modeling runs. Maryland generally followed the EPA’s preferred methodology and settings in the processing of the raw meteorological data into an AERMOD-ready format, and used AERSURFACE to best represent surface characteristics.

Hourly surface meteorological data records are read by AERMET, and include all the necessary elements for data processing. However, wind data taken at hourly intervals may not always portray wind conditions for the entire hour, which can be variable in nature. Hourly wind data may also be overly prone to indicate calm conditions, which are not modeled by AERMOD. In order to better represent actual wind conditions at the meteorological tower, wind data of 1 minute duration was provided from the same instrument tower, but in a different formatted file to be processed by a separate preprocessor, AERMINUTE. These data were subsequently integrated into the AERMET processing to produce final hourly wind records of AERMOD-ready meteorological data that better estimate actual hourly average conditions and that are less prone to over-report calm wind conditions. This allows AERMOD to apply more hours of meteorology to modeled inputs, and therefore produce a more complete set of concentration estimates. As a guard against excessively high concentrations that could be produced by AERMOD in very light wind conditions, Maryland set a minimum threshold of 0.5 meters per second in processing meteorological data for use in AERMOD. This approach is consistent with a March 2013 EPA memo titled, “Use of ASOS meteorological data in AERMOD dispersion Modeling.” In setting this threshold, no wind speeds lower than this value would be used for determining concentrations. This threshold was specifically applied to the 1-minute wind data.

#### *Modeling Parameter: Geography and Terrain*

The Fort Smallwood complex sits on the western shore of the Chesapeake Bay southeast of the City of Baltimore. Elevations are relatively flat in the immediate area of Wagner since it resides on the Atlantic Coastal Plain. Terrain rises to the northwest as the Atlantic Coastal Plain physiographic province gives way to the higher terrain of the Piedmont.

To account for these terrain changes, the AERMAP terrain program within AERMOD was used to specify terrain elevations for all the receptors. The source of the elevation data incorporated into the model was the USGS National Elevation Database.

*Modeling Parameter: Background Concentrations of SO<sub>2</sub>*

The Modeling TAD offers two mechanisms for characterizing background concentrations of SO<sub>2</sub> that are ultimately added to the modeled design values: 1) a “first tier” approach, based on monitored design values, or 2) a temporally varying approach, based on the 99<sup>th</sup> percentile monitored concentrations by hour of day and season or month. For the Wagner area of analysis, Maryland chose to use a seasonally varying by wind sector background from the Beltsville SO<sub>2</sub> monitor. The Essex monitor is the closest monitor to the Wagner and Fort Smallwood complex (approximately 15 km northeast). Due to its close proximity to Wagner and other nearby large SO<sub>2</sub> sources, the Essex monitor is probably influenced by these sources bringing up the possibility of “double counting” where source contributions are being made in both the modeling analysis and the representative background concentration. Using Beltsville, located in Maryland’s Prince George’s County approximately 33 km southwest of Wagner and the Fort Smallwood Complex, minimizes this possibility. .

*Summary of Modeling Results*

The AERMOD modeling parameters, as supplied by additional information from Maryland during the comment period for the Wagner area of analysis are summarized below in Table 5.

**Table 5. AERMOD Modeling Parameters for the Wagner Area of Analysis**

Wagner, MD Area of Analysis	
AERMOD Version	15181
Dispersion Characteristics	Rural
Modeled Sources	4
Modeled Stacks	9
Modeled Structures	16
Modeled Fence lines	2
Total receptors	17,000
Emissions Type	Actual (Hourly Varying)
Emissions Years	2013-15
Meteorology Years	2013-15
Surface Meteorology Station	BWI Airport, MD
Upper Air Meteorology Station	Dulles Airport, VA
Methodology for Calculating Background SO <sub>2</sub> Concentration	Wind Sector, Seasonal
Calculated Background SO <sub>2</sub> Concentration	Varies by Wind Sector and Season

The results presented below in Table 6 show the magnitude and geographic location of the highest predicted modeled concentration based on actual emissions.

**Table 6. Maximum Predicted 99th Percentile 1-Hour SO<sub>2</sub> Concentration in the Wagner Area of Analysis Based on Actual Emissions**

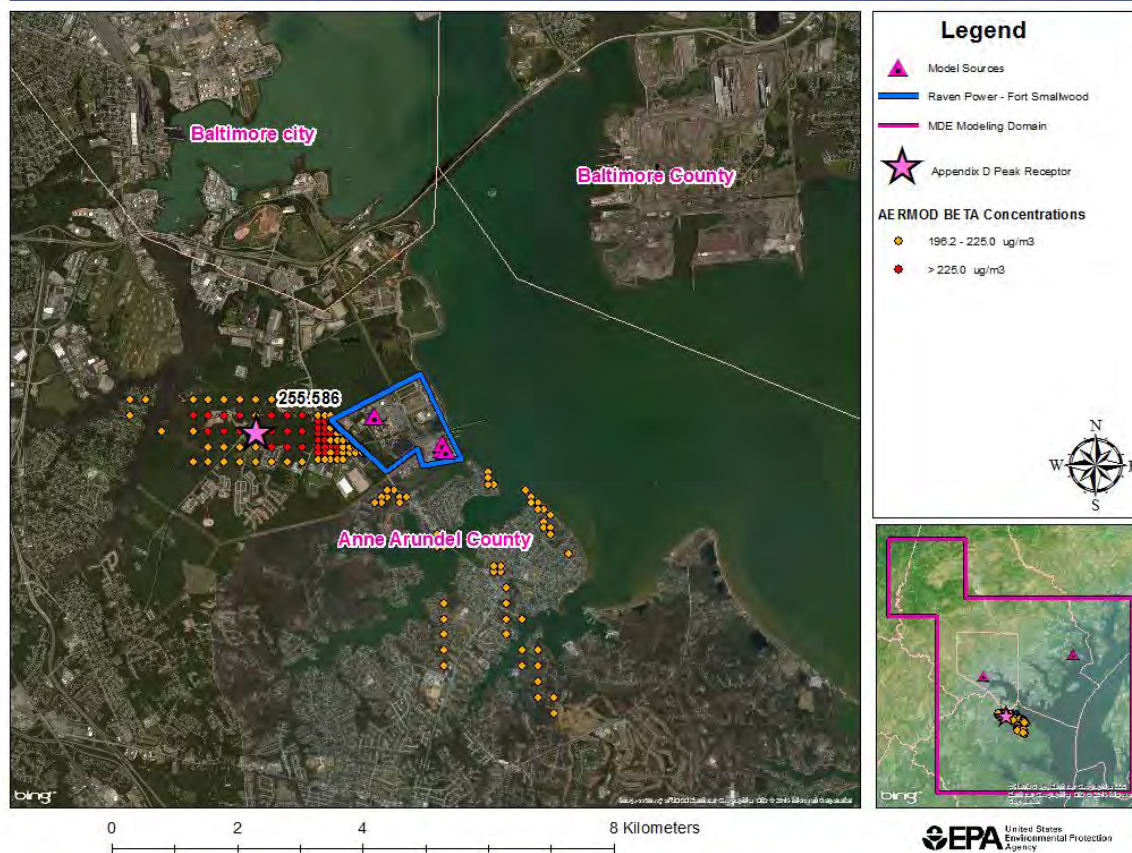

Averaging Period	Data Period	Receptor Location		SO <sub>2</sub> Concentration (µg/m <sup>3</sup> )	
		UTM z18 E (m)	UTM z18 N (m)	Modeled (including background)	NAAQS
99th Percentile 1-Hour Average	2013-15	365075	4337890	255.586	196.5*

\*Equivalent to the 2010 SO<sub>2</sub> NAAQS set at 75 ppb

Modeling included in Maryland's Appendix D indicates that the highest predicted 3-year average 99<sup>th</sup> percentile 1-hour average concentration within the chosen modeling domain is 255.6 µg/m<sup>3</sup>, or ~98 ppb. This modeled concentration included a background SO<sub>2</sub> concentration, and is based on actual emissions from the Brandon Shores, C.P. Crane, Wagner, and the Wheelabrator Baltimore Incinerator. Figure 4 shows the model receptors that exceed the 1-hour SO<sub>2</sub> NAAQS. Violating model receptors in Maryland's Appendix D modeling analysis occur within 6 km of the Fort Smallwood Complex and Wagner. The model peak concentration occurs to the west of Wagner with additional violating receptors also located to the south and southwest.

**Figure 4. Maximum Predicted 99<sup>th</sup> Percentile 1-Hour SO<sub>2</sub> Concentrations in the Wagner Area of Analysis Based on Actual Emissions**

## MDE April 19, 2016 Submittal - App D - BETA Modeling Analysis

### Emissions and Emissions-Related Data

A thorough discussion of emissions from Wagner and other nearby sources can be found in the TSD for our intended designation, however, some additional emissions and emissions-related information is provided in this final TSD. With regards to relevant emissions information, the EPA further considered the emission rates and limits of C.P. Crane and the Wheelabrator Baltimore Incinerator. Crane has a significantly higher hourly emission limits (Table 7) and actual hourly emission rates (Table 8) in comparison to the Baltimore Incinerator. While both Crane and the Baltimore Incinerator have similar annual emission limits, the hourly limit is more important due to the 1-hour SO<sub>2</sub> NAAQS. Furthermore, Crane does not have any SO<sub>2</sub> emission control devices installed and operating, whereas Wheelabrator operates with a “slaked lime” spray dryer absorber (SDA). Each of Crane’s two (2) unit hourly emission limits are over 17 times greater than the Baltimore Incinerator’s. Crane’s maximum actual hourly emission rates are 8 to 14 times higher than the Baltimore Incinerator. Based on this emissions information, the impact of Crane’s emissions on the area’s air quality is likely much greater than that of the Baltimore Incinerator.

**Table 7. Allowable Emission Limits based on Crane and Baltimore Incinerator Title V Permits**

Source	Hourly Limit	Boiler Rating	Hourly Limit (lbs/hr)	Annual Limit (tpy)
Crane Unit 1	3.5 lbs/MmBTU	1,865MmBTU/hr	~6,527.50	1,532
Crane Unit 2	3.5 lbs/MmBTU	1,865MmBTU/hr	~6,527.50	1,646
Wheelabrator Baltimore Incinerator			375	1,478

**Table 8. Modeled (Actual) Emission Rates**

Source	Rate	lbs/hr	Total (tpy)		
			2013	2014	2015
Crane Unit 1	Variable	0.0 to 2,966.7	831.3	573.4	387.9
Crane Unit 2	Variable	0.0 to 5,409.7	2,140.3	1,313.8	953.9
Wheelabrator Baltimore Incinerator	Fixed	100	438	438	438

Maryland's BETA Adjust U\* modeling analysis included a culpability analysis which showed source contribution for each receptor that exceeded the NAAQS; this area was confined to the area immediately surrounding Wagner (see Figure 4). Specifically, for violating receptors surrounding the Wagner generating station, modeled impacts from Crane Units 1 and 2 are four (4) times higher than modeled impacts from the Wheelabrator Baltimore Incinerator. Crane's maximum modeled impact to violating receptors in the Wagner area is  $4.9 \mu\text{g}/\text{m}^3$  versus the Baltimore Incinerators maximum modeled impact to violating receptors, which is  $1.2 \mu\text{g}/\text{m}^3$ .

Additionally, Crane's modeled impact in the immediate Wagner area may be greater than currently stated. First, modeled impacts are based on actual emissions, which may not reflect Crane's impact if in the future it emits closer to its hourly permitted emission rates (see Table 7). Actual maximum hourly rates for Crane are only 45% of permitted limits for Unit 1 and 83% of permitted limits for Unit 2. This estimate may be conservative since no analysis was done to examine how often both of Crane's units operate during the same hour; Crane's combined actual hourly emission rates may be a much smaller fraction of its combined hourly permitted emission rate. Second, the actual hourly model rates for Crane may not have occurred during worst-case meteorological conditions. Crane's hourly emissions were set to zero (0) for nearly 60% of the hours in the model simulation. By contrast, the Baltimore Incinerator's model impacts were fully assessed since it emitted during all hours of the simulation, thus including worst-case meteorological conditions. With so many hours at Crane set to zero (0) there is no way of assuring the units were on during the worst-case meteorological conditions so modeled impacts for Crane could actually be much higher. For reasons outlined in this section, the EPA has

determined that it is appropriate to include Crane in the Anne Arundel County and Baltimore County nonattainment area.

### Jurisdictional Boundaries

Once the geographic area of analysis associated with Wagner, other nearby sources of SO<sub>2</sub>, and background concentration is determined, existing jurisdictional boundaries are considered for the purpose of informing our final nonattainment area, specifically with respect to clearly defined legal boundaries. Given that existing jurisdictional boundaries do not appear suitable for defining the nonattainment area surrounding Wagner (discussed in detail in the TSD for our intended designation, p. 47-49), the EPA's position is that an alternative to using jurisdictional boundaries is to draw a circle around the sources most impacting the area's air quality and all modeled violating receptors. Similar to the EPA's proposed nonattainment area boundary, and considering the new modeling analysis submitted by Maryland that uses the BETA Adjust U\* option, the EPA finds that a circle drawn with a radius extending out 26.8 km from Wagner's Unit 3 stack (located at 39.17765N latitude, 76.52752W longitude) is an appropriate boundary. Such a circle encloses portions of Anne Arundel and Baltimore Counties, which contain all of the violating receptors and sources most impacting the area for the SO<sub>2</sub> NAAQS.

Maryland's April 19, 2016, submittal provided a recommended boundary around Wagner consisting of roads and a land/water interface. The EPA disagrees with such a boundary in that it only includes the modeled violations within approximately 6 kilometers of Wagner and does not include the impacts of the C.P. Crane power plant. Additionally, the EPA does not find such a boundary suitable because roads have the potential to shift, which could alter the nonattainment area boundary. The EPA finds that our final nonattainment area, consisting of portions of Anne Arundel and Baltimore Counties that are within 26.8 kilometers of Herbert A. Wagner's Unit 3 stack, which is located at 39.17765N latitude, 76.52752W longitude, are comprised of clearly defined legal boundaries, and we find these boundaries to be a suitably clear basis for defining our final nonattainment area.

### Conclusion

After careful evaluation of the state's recommendations, all timely comments and information received during the state and public comment period, and additional relevant information as discussed in this document, the EPA determines that the area around Wagner is not meeting the NAAQS, and therefore is designating the area as nonattainment for the 2010 SO<sub>2</sub> NAAQS. Specifically, the area is comprised of portions of Anne Arundel and Baltimore Counties that are within 26.8 kilometers of Herbert A. Wagner's Unit 3 stack, which is located at 39.17765N latitude, 76.52752W longitude. After taking into consideration all of the air dispersion modeling analyses the EPA received both prior to and during the comment period, the EPA believes Maryland's modeling analysis, which uses the BETA Adjust U\* option, showing SO<sub>2</sub> NAAQS violations occurring in the immediate vicinity of Wagner, to be most representative of actual air quality in the area. The EPA finds that Maryland's BETA Adjust U\* AERMOD simulation included in Maryland's Appendix D most closely follows the Modeling TAD and EPA's March 20, 2015 guidance, and is therefore the most accurate representation currently available of air quality in the Wagner area.

Additionally, based on the weight of evidence of available source contribution information and emissions data, the EPA finds that the C.P. Crane power plant in neighboring Baltimore County contributes to the SO<sub>2</sub> NAAQS violations occurring in the immediate vicinity of Wagner, and as such, believes a nonattainment boundary which includes Crane is appropriate. Furthermore, the EPA has determined based on the weight of evidence of available source contribution information, emissions data, and an installed and operational emissions control device at Wheelabrator, that the Wheelabrator Baltimore Incinerator in neighboring Baltimore City should not be included in the nonattainment area.

At this time, our final designation for the state only applies to this area and the other area contained in this final TSD. Consistent with the court-ordered schedule, the EPA will evaluate and designate all remaining undesignated areas in Maryland by either December 31, 2017, or December 31, 2020.

## **Technical Analysis for Baltimore City, Maryland Unclassifiable/Attainment Area**

### Introduction

In its April 19, 2011, submission to the EPA for the initial designations for the 2010 SO<sub>2</sub> NAAQS, Maryland recommended that Baltimore City be designated as unclassifiable. Maryland did not update its recommendation for Baltimore City in its 2015 updated recommendation.

On February 16, 2016, the EPA notified Maryland that we intended to designate the Baltimore City, Maryland area as unclassifiable/attainment, based on our view that the area was meeting the NAAQS and not contributing to the violations occurring in Baltimore County and Anne Arundel County. Additionally, we informed Maryland that our intended boundary for Baltimore City for the unclassifiable/attainment area consisted of Baltimore City's jurisdictional boundary.

Our intended designation and associated boundaries were based on air dispersion modeling showing persuasive evidence that SO<sub>2</sub> NAAQS violations are not occurring in Baltimore City. Detailed rationale, analyses, and other information supporting our intended designation for this area can be found in the TSD for our intended designation for Maryland, and this document along with all others related to this rulemaking can be found in Docket ID EPA-HQ-OAR-2014-0464.

The EPA is explicitly incorporating and relying upon the analyses and information presented in the TSD for our intended designation for the purposes of our final designation for this area, except to the extent that any new information submitted to the EPA or conclusions presented in this final TSD and our response to comments document (RTC), available in the docket, supersede those found in the TSD for our intended designation. Namely, Maryland's new modeling analysis discussed earlier in this document which relied upon the BETA Adjust U\* option shows no NAAQS violations in Baltimore City. The EPA finds that Maryland's BETA Adjust U\* AERMOD simulation included in Maryland's Appendix D most closely follows the Modeling TAD and the EPA's March 20, 2015, guidance, and therefore continues to support an

unclassifiable/attainment designation for Baltimore City (*See* the “State of Maryland Appendix D Modeling Summary” section discussed above).

Given these modeling results and that there are no large SO<sub>2</sub> emissions sources located within Baltimore City that could be impacting areas outside of Baltimore City, as well as no violating monitors in the area and limited terrain, the EPA believes there is persuasive evidence to support a conclusion that Baltimore City is meeting the NAAQS and is not contributing to a nearby area that does not meet the NAAQS and that a designation of unclassifiable/attainment is appropriate. Therefore, the EPA designates Baltimore City as unclassifiable/attainment for the 2010 SO<sub>2</sub> NAAQS.

#### Jurisdictional Boundaries:

The EPA notes that our final unclassifiable/attainment area, consisting of Baltimore City is comprised of a clearly defined legal boundary, and we find this boundary to be a suitably clear basis for defining our final unclassifiable/attainment area.

#### Conclusion

After careful evaluation of the Maryland’ recommendation, all timely comments and information received during the state and public comment period, and additional relevant information as discussed in this document, the EPA is designating Baltimore City as unclassifiable/attainment for the 2010 SO<sub>2</sub> NAAQS. Specifically, the area is comprised of Baltimore City’s jurisdictional boundary.

## Appendix C-2b

### Graphs of Five-Year Modeling Runs, 2012-2017 Brandon Shores & Wagner Generating Stations

#### Brandon Shores Generating Station, Case 1

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 3

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 4

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 5

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 6

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 7

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 8

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 9

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 10

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 11

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 12

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 13

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 14

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 15

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 16

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 17

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 18

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 19

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 20

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 21

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 22

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 23

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 24

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 25

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 26

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 27

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 28

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 29

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 30

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 31

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 32

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 33

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 34

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 35

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 36

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 37

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 38

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 39

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 40

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 41

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 42

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 43

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 44

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 45

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 46

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 47

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 48

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 49

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 50

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 51

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 52

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 53

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 54

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 55

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 56

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 57

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 58

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 59

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 60

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 61

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 62

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 63

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 64

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 65

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 66

Case1:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 67

 RRE - Model Run 64

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 65

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 66

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 67

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 68

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 69

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 70

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 71

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 72

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 73

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 74

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 75

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 76

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 77

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 78

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 79

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 80

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 81

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 85

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 86

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 87

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 88

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 89

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 90

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 91

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 92

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 93

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 94

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 95

Case2:  
 Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
 RRE - Model Run 96

Case2:  
Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
RRE - Model Run 97

Case2:  
Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
RRE - Model Run 98

Case2:  
Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
RRE - Model Run 99

Case2:  
Brandon Shores Merged Stack, Running 30-Day Average Emission Rate  
RRE - Model Run 100

**Brandon Shores Generating Station, & Wagner Generating Station Unit 3 – Case 1**

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 4

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 5

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 6

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 7

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 8

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 9

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 10

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 11

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 12

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 13

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 14

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 15

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 16

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 17

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 18

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 19

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 20

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 21

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 22

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 23

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 24

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 25

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 26

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 27

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 28

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 29

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 30

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 31

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 32

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 33

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 34

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 35

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 36

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 37

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 38

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 39

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 40

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 41

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 42

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 43

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 44

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 45

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 46

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 47

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 48

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 49

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 50

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 51

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 52

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 53

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 54

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 55

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 56

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 57

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 58

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 59

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 60

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 61

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 62

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 63

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 64

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 65

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 66

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 67

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 68

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 69

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 70

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 71

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 72

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 73

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 74

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 75

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 76

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 77

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 78

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 79

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 80

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 81

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 82

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 83

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 84

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 85

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 86

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 87

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 88

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 89

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 90

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 91

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 92

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 93

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 94

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 95

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 96

Case1:  
Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 97

Case1:  
Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 98

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 99

Case1:  
 Brandon Shores Merged Stack & Wagner Unit 3, Running 30-Day Average Emission Rate  
 RRE - Model Run 100

## Wagner Generating Station, Unit 3 – Case 1

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 1

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 2

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 3

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 4

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 5

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 6

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 7

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 8

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 9

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 10

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 11

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 12

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 13

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 14

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 15

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 16

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 17

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 18

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 19

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 20

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 21

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 22

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 23

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 24

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 25

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 26

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 27

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 28

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 29

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 30

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 31

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 32

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 33

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 34

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 35

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 36

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 37

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 38

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 39

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 40

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 41

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 42

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 43

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 44

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 45

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 46

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 47

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 48

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 49

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 50

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 51

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 52

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 53

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 54

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 55

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 56

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 57

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 58

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 59

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate  
RRE - Model Run 60

Case1:  
Wagner Unit 3, Running 30-Day Average Emission Rate

## Appendix C-4: EPA Findings Regarding the Air Dispersion Modeling and Methods

### SO<sub>2</sub> questions and responses

**Goold, Megan**

Apr 23, 2019, 3:41 PM

to Roger Thunell, Tim

Hi Roger – Below are our responses to your recent questions about the emission limits and modeling for the Baltimore/ Anne Arundel SO<sub>2</sub> Attainment plan. Please let me know if you have any further questions.

Thanks,  
Megan

#### **MDE question:**

Megan:

Could EPA R3 make this statement about the Anne Arundel County and Baltimore County SO<sub>2</sub> nonattainment area modeling/limits? Then we could start working on the actual permit conditions for compliance within a consent agreement.

EPA Region 3 has reviewed the modeling protocols, modeling files and modeling report for the Anne Arundel County and Baltimore County SO<sub>2</sub> nonattainment area. EPA Region 3 has determined that the modeling was conducted in accordance with EPA guidance and the proposed limitations on operating parameters and SO<sub>2</sub> rates are sufficient to meet the 2010 1-hour SO<sub>2</sub> National Ambient Air Quality Standard (NAAQS). The specific permit restrictions for each of the units must be permanent, federally enforceable and be a direct reflection of the modeling submitted as part of the modeling report.

#### **EPA Response:**

The purpose of EPA's early review is to assist states in the development of SIPs and to identify potential problems, but not to give a pre-approval to any particular approach. EPA has reviewed MDE's modeling protocols, modeling files, and modeling report for the Anne Arundel County and Baltimore County SO<sub>2</sub> nonattainment area, and understands that MDE will develop consent orders with the facilities to adopt the emission and operational limits that modeled attainment to meet the 2010 1-hour National Ambient Air Quality Standard (NAAQS). EPA suggests that any changes in the Nonattainment area (since the completion of the modeling) such as background concentration, model version updates and source closures be included (in at least) the written documentation of the SIP. The specific permit restrictions for each of the units must be quantifiable (i.e., a specific amount of emission reduction can be ascribed to the measures), fully enforceable (specifying clear, unambiguous and measurable requirements for which compliance can be practicably determined), replicable (the procedures for determining compliance are sufficiently specific and non-subjective so that two

independent entities applying the procedures would obtain the same result), and accountable (source specific limits must be permanent and must reflect the assumptions used in the modeling analysis).

**MDE Question:**

Does EPA agree with the footnote attached to Table 7-1: Proposed SO<sub>2</sub> Enforceable Limits that Brandon Shores Units 1 and 2 (combined) does not need a separate individual permit limit. Raven/Talen states that a separate BS1/BS2 limit is not required as it is included in the Fort Smallwood Complex 30-day limit.

Does EPA agree with this conclusion that a stand alone SO<sub>2</sub> permit limitation is not required for the merged BS1/BS2 stack because of the proposed BS1/BS2/W 30-day limit and the proposed operational constraints on BS1/BS2?

**EPA Response:**

Yes, EPA agrees that only one 30-operating day limit (combined coal unit) would be needed for Brandon Shores 1 and 2, and Wagner Unit 3 (i.e., no unit specific limits for Brandon Shores, however there is a stand-alone 30-day limit for Wagner Unit 3). AECOM's Case 2 runs use the identical emission rate as the combined coal rate limit (3,860 lbs/hr) so one rate was used in the modeling analysis in support of the proposed limits, whether Wagner was on or off. The supplemental limits as listed in Table 7-1 for Brandon Shores and Wagner would also be included as permit limits.

to Megan, Tim

Thanks for the response. I have a clarification.

MDE did not mean to ask for pre-approval of the SIP.

MDE is asking EPA if the modeling protocols, modeling files and modeling report were conducted in accordance with and meet EPA guidance.

Could EPA make this statement?

Goold, Megan

May 1, 2019, 4:10 PM

to Roger, Tim

Roger,

Sorry, I must have missed this email on Monday. Based on the information provided and reviewed to date, it appears that MDE's modeling protocols, modeling files, and modeling report are consistent with EPA guidance.

Thanks,

Megan Goold

U.S. Environmental Protection Agency Region 3

215-814-2027

---

EPA states:

"Based on the information provided and reviewed to date, it appears that MDE's modeling protocols, modeling files, and modeling report are consistent with EPA guidance."

"EPA has reviewed MDE's modeling protocols, modeling files, and modeling report for the Anne Arundel County and Baltimore County SO<sub>2</sub> nonattainment area, and understands that MDE will develop consent orders with the facilities to ***adopt the emission and operational limits that modeled attainment*** to meet the 2010 1-hour National Ambient Air Quality Standard (NAAQS)."

CONCLUSION:

The modeling protocols, files and report are consistent with EPA guidance and the emission and operational limits modeled attainment of the NAAQS.

DEC 27 2018

George S. Aburn, Director  
Maryland Department of the Environment  
Air and Radiation Management Administration  
1800 Washington Boulevard  
Baltimore, Maryland 21230

Dear Director Aburn:

Thank you for requesting pre-submittal review of the 1-Hour Sulfur Dioxide (SO<sub>2</sub>) National Ambient Air Quality Standard (NAAQS) State Implementation Plan (SIP) for the Anne Arundel County and Baltimore County, Maryland Nonattainment Area. The draft SIP revision included 30-day SO<sub>2</sub> emission limits at the Fort Smallwood Complex using a novel approach, namely a calendar-day compliance methodology, which allows for the inclusion of numerous nonoperating hours in the calculations for determining compliance with the limit. EPA has fully reviewed this request and considers this compliance approach to be inconsistent with EPA's Guidance for 1-hour SO<sub>2</sub> Nonattainment Area SIP Submissions (April 2014), and does not provide a supportable basis for determining that the draft SIP would ensure attainment of the NAAQS.

The 30-day averaging approach included in EPA's guidance was intended to provide additional operational flexibility for sources with significant variability in SO<sub>2</sub> emissions by allowing these sources to use longer-term average limits, provided EPA could determine that the longer-term average limits were able to ensure attainment. In determining whether a longer-term limit is able to ensure attainment of the 1-hour NAAQS, EPA considers many factors including, but not limited to, the method for determining compliance with the longer-term limit. Maryland has not demonstrated that its limit, using a compliance approach that makes compliance dependent in significant part on the frequency of operation and thus less dependent on how well emissions are controlled during operating hours, meets this critical criterion of reasonably showing attainment of the 1-hour standard.

Furthermore, the development of the 30-day average emission limit (which was derived as an average across an artificial emission distribution that includes a non-zero "floor" for emissions during nonoperating hours) is inconsistent with the proposed compliance determination method (which averages in zero emissions values during nonoperating hours and nonoperating days). EPA's 2014 Guidance underscores that the same data handling approach used for deriving the emission limit should be used for determining compliance with the limit. Additionally, the importance of treating nonoperating hours consistently throughout the development of, and compliance with, longer-term average emission limits is magnified for sources that have significant periods of nonoperation. EPA therefore considers the proportion of

nonoperating hours that are being included in the development of the longer-term average limit, and the method of demonstrating compliance with that limit, when evaluating whether such limits and compliance methods provide a reasonable basis for attainment of the NAAQS. EPA believes that there is greater risk for a NAAQS violation for units that adopt a longer term average limit and operate with significant periods of nonoperation throughout the year, which conversely could allow significant periods of potentially high emissions.

Determining compliance by averaging in zero values for nonoperating hours is especially problematic for units with significant periods of nonoperation throughout the year. In these cases, this compliance method could allow the unit to emit very high quantities of SO<sub>2</sub> during many operating periods. In this scenario, the unit could be in compliance with the 30-day average limit, while having very high emissions during many hours of the 30-day period that could lead to a violation of the NAAQS. Hence, it is particularly critical for this type of source to comply with the emission limits in a way that will minimize the magnitude and frequency of high emission values (i.e., comply with the limit only using operating hours). While Maryland has proposed additional supplemental limits to help constrain the frequency and magnitude of these high emissions spikes, the complexity created by the number of operating scenarios possible between multiple units at the Fort Smallwood facility do not reasonably lead EPA to conclude that the proposed limit and compliance method provide a comparable level of protection for a 1-hour NAAQS. As such, the draft SIP creates a high level of uncertainty in ensuring that compliance (as proposed in the draft SIP) with the proposed 30-day average emission limit would result in attainment.

My staff are available to discuss potential alternatives for the proposed emission limits and/or compliance options with your staff. If you have any questions, please do not hesitate to contact me or have your staff contact Ms. Megan Goold, at 215-814-2027.

Sincerely,

Cristina Fernandez, Director  
Air Protection Division

# 1. Introduction

## 1.1 Background

The United States Environmental Protection Agency (EPA) promulgated a 1-hour National Ambient Air Quality Standard (NAAQS) for SO<sub>2</sub> in 2010. The 1-hour SO<sub>2</sub> NAAQS has a level set at 75 ppb and the form of the standard is the average of the 99<sup>th</sup> percentile of the daily maximum 1-hour average concentrations realized in each of three consecutive calendar years (the “design value,” or DV).

The EPA is implementing the 2010 1-hour SO<sub>2</sub> NAAQS in an approach that involves either a dispersion modeling or monitoring approach to characterize local SO<sub>2</sub> concentrations near isolated emission sources. EPA’s Data Requirements Rule (DRR) was finalized on August 21, 2015 and H.A. Wagner Generating Station, Brandon Shores Generating Station and C.P. Crane Generating Station were informed that they are subject to the requirements in the DRR.

Talen Energy’s H.A. Wagner Generating Station and Brandon Shores Generating Station and PurENERGY’s C.P. Crane were modeled as part of the Consent Decree Round 2 phase of the SO<sub>2</sub> characterization process. Modeling was relied upon for the characterization, although all SO<sub>2</sub> monitors in the greater Baltimore area show attainment. On July 1, 2016, based upon use of default modeling approaches, EPA designated portions of Anne Arundel and Baltimore Counties around the H. A. Wagner power plant (Wagner) as non-attainment for the SO<sub>2</sub> primary NAAQS (see Figure 1-1). Per EPA, “a non-attainment area should contain the area violating the NAAQS as well as any adjacent areas (e.g., counties or portions thereof) that contain emissions sources contributing to the violation.”<sup>1</sup> Appendix A is EPA’s Technical Support Document (TSD)<sup>2</sup> for Maryland Area Designations for the 2010 SO<sub>2</sub> NAAQS. Due to its proximity to Wagner and Brandon Shores Generating Stations, C.P. Crane Generating Station (C.P. Crane) potential-to-emit (PTE) emission rate of 3.5 lb/MMBtu for each unit, EPA included the area around C.P. Crane in the nonattainment designation as well, even including areas with monitored concentrations below the NAAQS. The locations of the large SO<sub>2</sub> sources are shown in Figure 1-2.

The Maryland Department of the Environment (MDE) is required to prepare and submit a State Implementation Plan (SIP) to EPA that demonstrates the steps taken to achieve attainment of the NAAQS throughout the nonattainment area. The SIP includes a dispersion modeling study that indicates the expected SO<sub>2</sub> emission reductions required to bring the entire NAA into attainment within 5 years after the effective date of the nonattainment designation (by September 2021). It is desirable in the case of a monitored violation for the attainment demonstration to have controls in place 1 year in advance of the 5-year deadline in order to determine the effect of the controls on the monitor. In this case, there is no monitored violation at all, and the nonattainment area is solely based upon modeling with default assumptions. However, MDE has indicated that SIP emissions inventories are developed based on calendar year. Therefore, it seems appropriate for the proposed emission limits that model attainment to be in place by January 1, 2021.

Previous modeling protocol versions had been submitted by Talen Energy and PurENERGY separately for their respective facilities, while including the other’s facilities as background sources. MDE and EPA Region 3 requested that a single modeling protocol for Wagner, Brandon Shores and C.P. Crane be provided for the Anne Arundel and Baltimore Counties non-attainment area. Talen Energy and PurENERGY have both contracted AECOM to submit this modeling protocol and a subsequent report to satisfy the EPA requirements for 1-hour SO<sub>2</sub> State Implementation Plan (SIP) modeling demonstration for the Baltimore area. This modeling protocol, which is substantially based upon the modeling conducted for Talen Energy to date, summarizes the proposed dispersion modeling procedures to characterize future

<sup>1</sup> EPA Memorandum – Area Designations for the 2010 Revised Primary Sulfur Dioxide National Ambient Air Quality Standards – March 24, 2011.

<sup>2</sup> Docket EPA-HQ-OAR-2012-0233-0321.

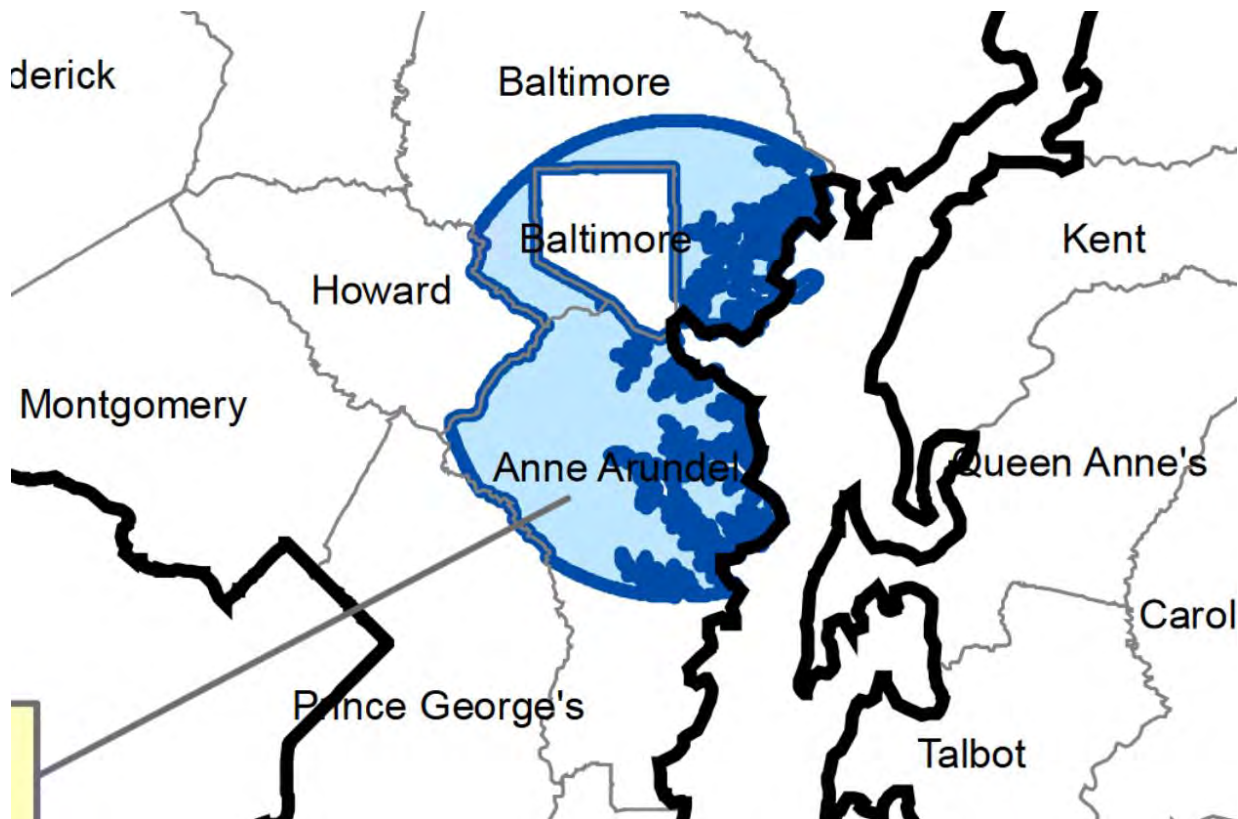

SO<sub>2</sub> concentrations for H.A. Wagner and Brandon Shores Generating Stations (also known as the Fort Smallwood Complex).

## 1.2 Document Organization

Section 2 provides a review of the ambient background monitor trends. Section 3 provides a discussion of SO<sub>2</sub> emission sources that will be included in the modeling demonstration. Section 4 outlines the modeling procedures to be used, including model options, meteorological data, receptors, and background concentrations. The initial modeling approach will be used to determine 1-hour average emission rates (EPA refers to these emission rates as “critical emissions values”) that show modeled NAAQS compliance, as discussed in Section 5.

EPA’s SIP development guidance for non-attainment areas<sup>3</sup> allows for the consideration of longer-term (e.g., 30-day) average emission rates that provide for comparable stringency with the critical emissions values. Section 6 discusses the procedures that may be used to establish longer-term average emission limits, as appropriate, for the major SO<sub>2</sub> sources in the NAA.

**Figure 1-1: Anne Arundel County and Baltimore County SO<sub>2</sub> Nonattainment Area**

**Figure 1-2: Locations of Current and Proposed Large SO<sub>2</sub> Sources in the Baltimore Area**

## 2. Review of Ambient Background Monitoring Data

There are two SO<sub>2</sub> monitors located in the Baltimore area, the Essex monitor (#24-005-3001) located northeast of the city and Howard University's Beltsville Laboratory (HU-Beltsville) monitor located southwest of the city. The HU-Beltsville monitor (#24-033-0030) began collecting data in 2006 and the Essex monitor began collecting data in 2003.

Table 2-1 shows the 1-hr SO<sub>2</sub> 99<sup>th</sup> percentiles of the daily 1-hour maximum concentrations from 2007 through 2016 for the Essex and HU-Beltsville SO<sub>2</sub> monitors. The 3-year average design values were above the then-future 1-hour NAAQS in the mid-2000's at the Essex monitor, but emissions reductions have reduced ambient monitor concentrations in the last five years and as such the design values have leveled off to approximately 25% of the 1-hour NAAQS at Essex and 12% of the NAAQS at HU-Beltsville.

**Table 2-1: 99<sup>th</sup> Percentile of the Daily 1-hour Maximum SO<sub>2</sub> Concentrations at the Essex and Beltsville Monitors**

Year	99 <sup>th</sup> Percentile of the Daily 1-hour Maximum Concentrations (ppb)		3-Year Average Design Values (ppb)	
	Essex	Beltsville	Essex	Beltsville
2007	129	34	--	--
2008	56	28	--	--
2009	54	24	79.7	28.7
2010	20	10	43.3	20.7
2011	27	12	33.7	15.3
2012	19	12	22.0	11.3
2013	21	7	22.3	10.3
2014	26	14	22.0	11.0
2015	18	8	21.7	9.7
2016	13	5	19.0	9.0

As shown in Figure 1-2, the Essex monitor is located near or downwind of all sources included in the modeling, and it is inside the nonattainment area (although the monitored concentrations are less than half of the NAAQS). Figure 2-1 shows a pollution rose for combined years 2012-2014. The wind direction data is taken from Baltimore-Washington International Airport, MD ASOS station. The predominant winds for the highest (dark red) concentrations are from the south/southwest (Fort Smallwood and Wheelabrator) and east/northeast (from C.P. Crane). As such, to avoid double-counting the SO<sub>2</sub> concentrations from the modeled sources with the regional background estimates, Talen Energy and PurENERGY propose to use the HU-Beltsville monitor when developing the ambient background concentrations to be included in this modeling analysis. The development of the background concentrations input to AERMOD is discussed in Section 4.7.

**Figure 2-1: Pollution Rose for Essex SO<sub>2</sub> Monitor for years 2014-2016**

### 3. Emission Source Inventory

#### 3.1 Sources to be Modeled

The EPA Technical Support Document (TSD; see excerpt in Appendix A) discusses SO<sub>2</sub> emission sources that were recommended by EPA to be included in the Maryland SIP modeling analysis.

Figure 1-1 shows the sources located within and near the Anne Arundel and Baltimore Counties, MD NAA. The sources include two boilers at C.P. Crane and Brandon Shores, four boilers at H.A. Wagner and an incinerator at Wheelabrator. Table 3-1 lists the sources to be modeled.

Typically, emission rates and stack parameters for the 1-hour SO<sub>2</sub> SIP modeling are held constant, similar to permit modeling, using full load conditions. However, the SO<sub>2</sub> Nonattainment Modeling Guidance does allow for some flexibility for sources that do not operate during all hours of the year or which have infrequent higher emission rates using the methodologies for rolling 30-day emission rates in Appendices B, C and D. As such, revised permitted emission rates for the units at Brandon Shores and Wagner are still to be determined, but will be included in the report in accordance with EPA's Nonattainment Modeling Guidance, using modeling procedures described in EPA's Appendix B. C.P. Crane will commit to 1-hour emission rate of 2,950 lb/hr (371.6912 g/s) as a cap for Units 1 and 2 combined. Based on EPA's National Emission Inventory (NEI) database and the inventory included in the SO<sub>2</sub> DRR, no other large stationary SO<sub>2</sub> sources (i.e. > 100 TPY) exist within 20 kilometers of the Fort Smallwood Complex.

##### 3.1.1 Brandon Shores Units

Brandon Shores Units 1 and 2 exhaust to a common stack with height and internal exit diameter as reported in Table 3-1. The average flow rate and weighted average temperature will be used in AERMOD, consistent with EPA Model Clearinghouse Memo 91-II-01.

Brandon Shores Units 1 and 2 are solid fossil fuel fired generating units with No. 2 oil used for start-up purposes. The following are descriptions of the approximate startup sequences of the units (subject to changing conditions and outcomes):

No. 2 oil ignitors are used in the boiler for approximately 16 hours, at which point main (coal) burners begin to be turned on. More coal burners are transitioned into service over the next 10 hours, approximately, at which point the turbine/generator becomes parallel with the grid. Minimum stable electric load is then typically achieved within the next 6 hours. All flue gases pass through the scrubber at all times; there is no bypass.

##### 3.1.2 H.A. Wagner Units

H.A. Wagner Unit 1 is a No. 6 oil or natural gas fired unit. Unit 3 is a coal fired unit with natural gas used for start-up. Unit 4 is a No. 6 oil fired unit with natural gas fired used for start-up. Wagner Unit 2 will cease burning coal and will have zero or insignificant SO<sub>2</sub> emissions by the end of June 2020 and therefore is not included as an SO<sub>2</sub> source for the modeling demonstration. The following are descriptions of the approximate startup sequences of the units (subject to changing conditions and outcomes):

Wagner Unit 1: natural gas ignitors are used in the boiler for approximately 8 hours, at which point main burners (gas or oil) are turned on and the turbine/generator becomes parallel with the grid. Minimum stable electric load is then typically achieved within the next hour.

Wagner Unit 3: natural gas ignitors are used in the boiler for approximately 6 hours, at which point main burners (coal) begin to be turned on. More coal burners are transitioned into service over the next 12

hours, approximately, at which point the turbine/generator becomes parallel with the grid. Minimum stable electric load is then typically achieved within the next four hours. Dry sorbent injection is commenced prior to achieving minimum load.

Wagner Unit 4: natural gas ignitors are used in the boiler for approximately 10 hours, at which point the main burners (oil) are turned on. More oil burners are transitioned into service over the next 8 - 10 hours, approximately, at which point, the turbine/generator becomes parallel with the grid. Minimum stable electric load is then typically achieved within the next two hours.

Future operational changes to be in place by January 2021 at Wagner include;

- Unit 1 will operate no more than 5% of the year (430 hours) on lower-sulfur (0.3%) No. 6 oil (otherwise it will fire on natural gas),
- Unit 3 will burn New Source Performance Standard (NSPS) compliant (lower-sulfur) coal,
- Implementation of a specialized sorbent is expected to improve SO<sub>2</sub> control efficiency with a dry sorbent injection system by 30% for Wagner Unit 3, and
- Unit 4 will operate no more than 5% of the year (430 hours) on lower-sulfur (0.3%) No. 6 oil,

### 3.1.3 C.P. Crane Units

C.P. Crane controls SO<sub>2</sub> emissions by means of burning lower sulfur coal than is currently permitted in tandem with a dry sorbent injection (DSI) system. For Crane, DSI has been known to decrease SO<sub>2</sub> by 5-10% depending on the quantity injected. The limit listed in Table 3-1 is based on current operations of the two units at C.P. Crane such that when either or both units are operating, they will not exceed this emission rate based on the coal currently being used by the facility.

C.P. Crane's Unit 1 had between 12 and 19 startup and shut down events per year during the 2014 to 2016 period. Startup operations lasted between 9 and 36 hours for Unit 1. During the first half of startup, the fuel type is a co-firing natural gas and coal, with the second half of startup using only coal. During the same 3-year period (2014-2016), C.P. Crane's Unit 2 had between 21 and 29 start up and shut down events per year. Unit 2 startups lasted between 5 and 24 hours, with natural gas firing only for the first half of startup and coal only for the second half of the startup period.

### 3.1.4 Intermittent Sources

Intermittent sources and transient conditions such as emergency generators, auxiliary boilers, and startup/shutdown operations will not be modeled as explained in the March 2011 EPA guidance document<sup>4</sup> for modeling 1-hour NO<sub>2</sub> and SO<sub>2</sub>. These emission sources are of insufficient duration and frequency to affect NAAQS compliance as shown in Table 3-2.

Wheelabrator**	47.250	96.01	2.130	485.93	22.55
**The Wheelabrator emission rate and source parameters were provided by MDE.					

**Table 3-2 Hours of Operation for Auxiliary Sources**

Facility	Source Description	2016 Operating Hours	2016 SO <sub>2</sub> Emissions (tons)
Brandon Shores	#1 Auxiliary Boiler: Zurn (Model 18M Keystone) No. 2 oil fired boiler	6	0.0601
	#2 Auxiliary Boiler: Zurn (Model 18M Keystone) No. 2 oil fired boiler	0	0.0000
	2 Quench Pumps (500 HP diesel-fired internal combustion engine) that supply water to the flue gas desulfurization (FGD) system in emergencies	29.5	0.0010
	Emergency generator (670 HP diesel-fired internal combustion engine) to provide back-up power	5.7	0.0003
H.A. Wagner	Combustion turbine (No. 2 oil fired) used to supply "black start" capability to H.A. Wagner and for peaking operation	44.7	0.3700
Crane	#2 Auxiliary Boiler fired by No. 2 oil (ULSD) used for supplying steam rated at 25 MMBtu/hour	7	0.0280
	#3 Auxiliary Boiler fired by natural gas with No. 2 fuel (ULSD) as a back-up and used for supplying steam rated at 62.5 MMBtu/hour	0 hours Oil, 4,248 hours Gas	0.0800
	Combustion turbine rated at 14 MW (summer capability) fired by No. 2 oil (ULSD)	55	0.011
	600 HP Emergency Generator (ULSD)	7	3E-05

## 3.2 Modeling Adjustments for Stacks with Moist Plumes

Wet or dry flue-gas desulfurization (FGD) scrubbers result in a flue gas stream that is either partially or fully saturated at the flue gas temperature (normally > 100 deg. F) and pressure. Upon discharge to the atmosphere, water vapor in the flue gas stream condenses to form water droplets, with a corresponding release of (latent) heat of condensation. This heat release acts to make the plume gases warmer and gives the plume a higher buoyant vertical velocity and the plume trajectory is often seen to have an upward trajectory a short distance downwind (see Figures 3-1 and 3-2). A small effect on plume behavior occurs as the droplets eventually evaporate on mixing (i.e., a cooling effect), but this effect occurs near final rise and it is accounted for in the moist plume modeling, IBJpluris, that is described below. The largest net rise is realized for the situation where the ambient air itself is near saturation. The discussion in Appendix B describes how this effect is modeled in AERMOD with the use of an hourly emissions file for each moist plume stack (as listed in Table 3-2, each with an effective hourly stack temperature that is higher than the actual stack temperature). This modeling approach may be applied to the Brandon Shores' sources listed in Table 3-1. Appendix C includes a document from EPA Region 4 discussing the use of source characterization techniques such as this that EPA did not consider to be a non-guideline option, thus it was not subject to the Appendix W, Section 3.2.2 alternative model evaluation criteria. Appendix D contains a supporting technical paper about AERMOIST and IBJpluris which has been published in the peer-reviewed journal *Atmospheric Environment*<sup>5</sup>. A justification package to support the use of AERMOIST for this modeling application was previously provided as a separate submittal where each facility was addressed. EPA is currently reviewing AERMOIST and has asked for additional documentation. Due to the likely delay in obtaining EPA approval of AERMOIST, the current modeling will not use this approach. Future modeling of the facility will consider AERMOIST if EPA approves it for general use.

## 4. Proposed Modeling Procedures

### 4.1 Dispersion Model Selection

This modeling analysis will utilize the most recent version of the AERMOD dispersion model (Version 16216r) to evaluate air quality impacts from the emission sources of interest. The AERMOD modeling system consists of two preprocessors and the dispersion model. AERMET is the meteorological preprocessor component and AERMAP is the terrain pre-processor component that characterizes the terrain and generates receptor elevations along with critical hill heights for those receptors. Table 4-1 summarizes the versions of AERMOD and its preprocessors.

**Table 4-1: Versions of AERMOD and Its Preprocessors to be Used in Modeling Demonstration**

Dispersion Model and Preprocessors	Version No.
AERMOD	16216r
AERMET	16216
AERMINUTE	15272
AERSURFACE	13016
BPIP-PRIME	04274
AERMAP	11103

### 4.2 Land Use Classification

One of the factors affecting input parameters to dispersion models is the presence of either rural or urban conditions near the source site and the meteorological site(s). The choice of rural or urban for dispersion conditions at the source site depends upon the land use characteristics within 3 kilometers of the facility being modeled (Appendix W to 40 CFR Part 51)<sup>6</sup>. Factors that affect the rural/urban choice, and thus the dispersion, include the extent of vegetated surface area, the water surface area, types of industry and commerce, and building types and heights within this area.

#### 4.2.1 Land Use Analysis for the Fort Smallwood Complex

An objective analysis using the Auer Method was conducted using ArcGIS to extract the land use categories within a 3 km radius centered on the Fort Smallwood Complex using the digitized 2011 NLCD data. Figure 4-1 shows the land categories within 3 km of the Fort Smallwood Complex. EPA mentions in their comment that for sites that have over 50% of the land use categorized as water, this could skew the analysis and lead to an improper “rural” designation. Table 4-2 shows that 39.7% of the land use within the 3 km radius consists of open water, which is below the 50% threshold. The land types defined as rural under the Auer Land Use Method is approximately 85%.

In addition, the land use surrounding the Fort Smallwood Complex was examined while ignoring the areas classified as water. This secondary analysis yields approximately 75% of the land cover as rural, still well above the 50% criteria threshold (shown in Table 4-3).

For these reasons and historically MDE has modeled the Fort Smallwood Complex as rural, we conclude that the designation of rural is appropriate for the modeling of the Fort Smallwood Complex for this application.

<sup>6</sup> EPA's Guideline on Air Quality Models, available at [https://www3.epa.gov/ttn/scram/appendix\\_w/2016/AppendixW\\_2017.pdf](https://www3.epa.gov/ttn/scram/appendix_w/2016/AppendixW_2017.pdf).

#### 4.2.2 Land Use Analysis for C.P. Crane

An objective analysis using the Auer Method was conducted using ArcGIS to extract the land use categories within a 3 km radius centered on C.P. Crane using the digitized 2011 NLCD data. Figure 4-2 shows the land categories within 3 km of C.P. Crane. EPA mentions in their comment that for sites that have over 50% of the land use categorized as water, this could skew the analysis and lead to an improper “rural” designation. Table 4-4 shows that 39.7% of the land use within the 3 km radius consists of open water, which is below the 50% threshold. The land types defined as rural under the Auer Land Use Method is approximately 85%.

In addition, the land use surrounding C.P. Crane was examined while ignoring the areas classified as water. This secondary analysis yields approximately 75% of the land cover as rural, still well above the 50% criteria threshold (shown in Table 4-5).

For these reasons and because MDE has previously modeled C.P. Crane as rural, we conclude that the designation of rural is appropriate for the modeling of the C.P. Crane for this application.

**Table 4-4: Land Use Analysis with 2011 NLCD for C.P. Crane**

Crane Study Area Auer's Analysis				Crane 3km Ring		
NLCD Value	NLCD 2011 Description	Auer's Code	Auer's Class	Cell Count	Percentage	Totals

### 4.3 Good Engineering Practice (GEP) Analysis

Federal stack height regulations limit the stack height used in performing dispersion modeling to predict the air quality impact of a source. Sources must be modeled at the actual physical stack height unless that height exceeds the Good Engineering Practice (GEP) formula stack height. If the physical stack height is less than the formula GEP height, the potential for the source's plume to be affected by aerodynamic wakes created by the building(s) must be evaluated in the dispersion modeling analysis.

A GEP formula stack height analysis has been performed for sources of interest located at the Brandon Shores, Wagner, C.P. Crane Generating Stations, and Wheelabrator in accordance with the EPA's "Guideline for Determination of Good Engineering Practice Stack Height" (EPA, 1985)<sup>7</sup>. A GEP stack height is defined as the greater of 65 meters (213 feet), measured from the ground elevation of the stack, or the formula height ( $H_g$ ), as determined from the following equation:

$$H_g = H_B + 1.5 L$$

where

$H_B$  is the height of the nearby structure which maximizes  $H_g$ , and

$L$  is the lesser dimension (height or projected width) of the building ( $H_B$ ).

For a squat structure, i.e., height less than projected width, the formula reduces to:

$$H_g = 2.5H_B.$$

In the absence of influencing structures, a "default" GEP stack height is credited up to 65 meters (213 feet). Both the height and the width of the building are determined through a vertical cross-section perpendicular to the wind direction. In all instances, the GEP formula height is based upon the highest value of  $H_g$  as determined from  $H$  and  $L$  over all nearby buildings over the entire range of possible wind directions. For the purposes of determining the GEP formula height, only buildings within  $5L$  of the source of interest are considered. The stacks to be included in the modeling demonstration and their commission dates are presented in Table 4-6.

**Table 4-6: Stack Commission Dates**

Facility	Stack	Commission Date
<b>C.P. Crane</b>	Unit 1	July 1961
	Unit 2	February 1963
<b>Brandon Shores</b>	Dual-flue FGD Units 1 & 2	2010
<b>H.A. Wagner</b>	Unit 1	February 1956
	Unit 2	January 1959
	Unit 3	August 1966
	Unit 4	August 1972
<b>Wheelabrator</b>	Incinerator	1985

The GEP analyses will be conducted with the latest version of the US EPA's Building Profile Input Program software (BPIP-PRIME version 04274). The locations and dimensions of the buildings/structures relative to the exhaust stacks for Brandon Shores, Wagner, C.P. Crane Generating Stations, and Wheelabrator are depicted in Figures 4-3 through 4-6. Building heights and the base elevations of buildings and stacks will be updated from previous modeling based on 2004 and 2014

<sup>7</sup> Available at <http://www.epa.gov/scram001/guidance/guide/gep.pdf>.

USGS LIDAR data<sup>8</sup> and confirmed with Google Earth Pro (shown in Figures 4-7 and 4-9) for the Fort Smallwood Complex and Wheelabrator. 3D representations of the buildings and stacks as output from BPIP-PRIME are shown in Figures 4-10 and 4-12. Historical LIDAR data are not available for the area near C.P. Crane, likely due to its proximity to Aberdeen Proving Ground.

## 4.4 Meteorological Data Processing

The meteorological data required for input to AERMOD will be created with the latest version of AERMET (16216) using the adjusted u<sub>\*</sub> option. This option is now a default option per the recently promulgated Appendix W. Hourly surface observations from Baltimore-Washington International Airport, MD along with concurrent upper air data from Sterling, VA will be used as input to AERMET with both 1-minute and 5-minute wind speed and direction data incorporated in AERMET Stage 2. The surface data (wind direction, wind speed, temperature, sky cover, and relative humidity) is measured 10 m above ground level<sup>9</sup>. The location of the anemometer in decimal degrees is 39.1733°N 76.6841°W. A wind rose for 2012-2016 is shown in Figure 4-13.

AERMET creates two output files for input to AERMOD:

- **SURFACE:** a file with boundary layer parameters such as sensible heat flux, surface friction velocity, convective velocity scale, vertical potential temperature gradient in the 500-meter layer above the planetary boundary layer, and convective and mechanical mixing heights. Also provided are values of Monin-Obukhov length, surface roughness, albedo, Bowen ratio, wind speed, wind direction, temperature, and heights at which measurements were taken.
- **PROFILE:** a file containing multi-level meteorological data with wind speed, wind direction, temperature, sigma-theta ( $\sigma_\theta$ ) and sigma-w ( $\sigma_w$ ) when such data are available. For this application involving representative data from the nearest NWS station, the profile file contained a single level of wind data and the temperature data.

AERMET requires specification of site characteristics including surface roughness ( $z_o$ ), albedo ( $r$ ), and Bowen ratio ( $B_o$ ). These parameters will be developed according to the guidance provided by US EPA in the recently revised AERMOD Implementation Guide<sup>10</sup> (AIG).

The AIG provides the following recommendations for determining the site characteristics:

1. The determination of the surface roughness length should be based on an inverse distance weighted geometric mean for a default upwind distance of 1 kilometer relative to the measurement site. Surface roughness length may be varied by sector to account for variations in land cover near the measurement site; however, the sector widths should be no smaller than 30 degrees.
2. The determination of the Bowen ratio should be based on a simple un-weighted geometric mean (i.e., no direction or distance dependency) for a representative domain, with a default domain defined by a 10-km by 10-km region centered on the measurement site.
3. The determination of the albedo should be based on a simple un-weighted arithmetic mean (i.e., no direction or distance dependency) for the same representative domain as defined for Bowen ratio, with a default domain defined by a 10-km by 10-km region centered on the measurement site.

The AIG recommends that the surface characteristics be determined based on digitized land cover data. EPA has developed a tool called AERSURFACE that can be used to determine the site characteristics based on digitized land cover data in accordance with the recommendations from the AIG discussed

<sup>8</sup> <http://earthexplorer.usgs.gov/> under Digital Elevation/LIDAR.

<sup>9</sup> Anemometer height obtained from National Weather Service ASOS Implementation site.

<http://www.nws.noaa.gov/ops2/Surface/asosimplementation.htm>

<sup>10</sup> Available at [https://www3.epa.gov/ttn/scram/7thconf/aermod/aermod\\_implmntn\\_guide\\_3August2015.pdf](https://www3.epa.gov/ttn/scram/7thconf/aermod/aermod_implmntn_guide_3August2015.pdf).

above. AERSURFACE<sup>11</sup> incorporates look-up tables of representative surface characteristic values by land cover category and seasonal category. AERSURFACE will be applied with the instructions provided in the AERSURFACE User's Guide.

At the direction of the reviewing agencies, a sensitivity analysis was conducted to determine the representativeness of the BWI airport surface characteristics to those at C.P. Crane and Fort Smallwood. To determine the representativeness of the BWI airport site for surface characteristics in comparison to the area surrounding Fort Smallwood, AERSURFACE was applied for a single 1-km sector around three sites (C.P. Crane, Fort Smallwood and BWI airport) using average moisture conditions. The results of the three AERSURFACE runs are presented in Table 4-7. Table 4-7 shows that the albedo values are very similar between the three sites. There is some variation in the Bowen ratios and surface roughness at the different sites. The surface roughness values are all relatively low (less than 0.16 meters), with BWI having a surface roughness value between C.P. Crane and Fort Smallwood.

Based on results of the sensitivity analysis, we propose using monthly surface roughness and albedo from the BWI airport, with the Bowen ratio from Fort Smallwood. The annual values for comparison between the three sites are highlighted blue in Table 4-7.

**Table 4-7: AERSURFACE Land Use Comparison**

Site	Annual Average Land Use		
	Albedo	Bowen Ratio	Z <sub>0</sub> (m)
BWI Airport	0.16	0.76	0.051
C.P. Crane	0.13	0.22	0.024
Fort Smallwood	0.13	0.33	0.157

The current version of AERSURFACE (Version 13016) supports the use of land cover data from the USGS National Land Cover Data 1992 archives<sup>12</sup> (NLCD92). The NLCD92 archive provides data at a spatial resolution of 30 meters based upon a 21-category classification scheme applied over the continental U.S. The AIG recommends that the surface characteristics be determined based on the land use surrounding the site where the surface meteorological data were collected.

As recommended in the AIG for surface roughness, the 1-km radius circular area centered at the meteorological station site can be divided into sectors for the analysis; the default 12 sectors will be used for this analysis.

In AERSURFACE, the various land cover categories are linked to a set of seasonal surface characteristics. As such, AERSURFACE requires specification of the seasonal category for each month of the year. The following five seasonal categories are supported by AERSURFACE, with the applicable months of the year specified for this site.

1. Midsummer with lush vegetation (June-August).
2. Autumn with un-harvested cropland (September- November).
3. Late autumn after frost and harvest, or winter with no snow (December - February)
4. Winter with continuous snow on ground (none).
5. Transitional spring with partial green coverage or short annuals (March - May).

<sup>12</sup> See additional information at <http://landcover.usgs.gov/natl/landcover.php>.

AECOM reviewed snow cover data<sup>13</sup> for BWI during the 2012-2016 period to determine if any winter month had snow cover for more than half of the days in the month. BWI reported only eight non-consecutive days with snow depth in January 2014 (26% of the month), and seven consecutive days in February 2014 (25% of the month). During 2015, however, February had 14 occurrences of days with snow depth qualifying this month to be characterized as “winter with continuous snow on ground”. Therefore, a separate AERSURFACE run was conducted to account for this month of snow for 2015. The two runs were then concatenated together to represent each month’s characterization correctly.

For Bowen ratio, the land use values are linked to three categories of surface moisture corresponding to average, wet, and dry conditions. The surface moisture condition for the site may vary depending on the meteorological data period for which the surface characteristics will be applied. AERSURFACE applies the surface moisture condition for the entire data period. Therefore, if the surface moisture condition varies significantly across the data period, then AERSURFACE can be applied multiple times to account for those variations.

As such, the surface moisture condition for each season will be determined by comparing precipitation for the period of data to be processed to the 30-year climatological record, selecting “wet” conditions if precipitation is in the upper 30<sup>th</sup>-percentile, “dry” conditions if precipitation is in the lower 30<sup>th</sup>-percentile, and “average” conditions if precipitation is in the middle 40<sup>th</sup>-percentile. The 30-year precipitation data set to be used in this modeling will be taken from the National Climatic Data Center<sup>14</sup>.

The monthly designations of surface moisture that will be input to AERSURFACE are summarized in Table 4-8.

## 4.5 Receptors to be Modeled

Receptors are placed in nested Cartesian grids centered on the Fort Smallwood Complex and C.P. Crane with the following spacing:

- Every 25 meters along the ambient boundary,
- Every 100 meters out to a distance of 15 km, and
- Every 500 meters between 15 and 25 km.

The current version of AERMAP has the ability to process USGS National Elevation Dataset (NED) data in place of Digital Elevation Model files. The appropriate file for 1-arc-second, or 30-m, NED data will be obtained from the Multi-Resolution Land Characteristics Consortium (MRLC) link at <https://viewer.nationalmap.gov/viewer/>. The receptor grid is shown in Figures 4-14, 4-15 and 4-16.

In the unlikely case that the peak concentration might occur beyond 25 km, then additional receptors beyond the 25-km distance will be added as appropriate. The results from this receptor grid will be included in the model assessment report to the agency reviewers.

Receptors will not be placed on Talen Energy property that is not accessible to the public. Public access is restricted along the property boundary for the H.A. Wagner and Brandon Shores Power Plants by: 1) a physical fence (including gates) as denoted by the yellow lines in Figure 4-17 and 2) no trespassing signs along the orange lines in Figure 4-17 that extends the immediate waters alongside the fuel unloading pier.

Receptors will not be placed on C.P. Crane property that is not accessible to the public. Public access is restricted along the property boundary for the C.P. Crane Generating Station by: 1) a physical fence (including gates) as denoted by the yellow lines in Figure 4-18 and 2) a retaining wall prevents public vessels from entering the nearby waters of C.P. Crane as denoted by the light green line in Figure 4-18. A close-up photo taken just offshore shows the retaining wall from a different angle in Figure 4-19.

With multiple sources included as part of the proposed modeling demonstration, an analysis will be performed to ensure there are no NAAQS violations occurring within the ambient air boundary at Fort

Smallwood Complex from C.P. Crane sources and within C.P. Crane's ambient air boundary from sources at the Fort Smallwood Complex. To accomplish this, receptors will be placed on C.P. Crane's property and all modeled sources (excluding C.P. Crane stacks) will be modeled at these receptors to ensure there is not a NAAQS violation. Additionally, receptors will be placed on Fort Smallwood's property and all modeled sources (excluding Brandon Shores and H.A. Wagner stacks) will be modeled at these receptors to ensure there is not a NAAQS violation.

## 4.6 Model Configurations and Options

AERMET (version 16216) and AERMOD (version 16216r) will be run with the updated "ADJ\_U\*" option in AERMET and the DEFAULT option in AERMOD to use the ADJ\_U\* meteorological data. Appendix W states, "EPA is adopting the proposed ADJ\_U\* option in AERMET as a regulatory option for the use in AERMOD for sources using standard NWS airport meteorological data, site-specific meteorological data without turbulence parameters, or prognostic meteorological inputs derived from prognostic meteorological models." For this modeling demonstration, standard NWS airport meteorological data from the Baltimore-Washington International (BWI) Airport and the ADJ\_U\* option is appropriate.

## 4.7 Background Concentrations

The HU-Beltsville, MD monitor (Site #24-033-0030), which is located about 33 km to the southwest of the Fort Smallwood Complex and 52 km southwest of C.P. Crane, in Prince Georges County, will be used to determine the uniform regional background component for the NAAQS SO<sub>2</sub> modeling. EPA's March 2011 clarification memo<sup>15</sup> regarding 1-hour SO<sub>2</sub> NAAQS modeling allows for an approach using the 99<sup>th</sup> percentile monitored values whereby the background values vary by season and by hour of the day. AECOM will apply this approach to its modeling, using data from the 3-year period of 2014 – 2016 to be added to the three years of modeled concentrations. The SO<sub>2</sub> concentrations that will be used are listed in Table 4-9. Figure 4-20 shows a plot of the hourly background values by season and hour.

According to the EPA's "Table 5c Monitoring Site Listing for Sulfur Dioxide 1-Hour NAAQS" ([https://www.epa.gov/sites/production/files/2016-07/so2\\_designvalues\\_20132015\\_final\\_07\\_29\\_16.xlsx](https://www.epa.gov/sites/production/files/2016-07/so2_designvalues_20132015_final_07_29_16.xlsx)), the completeness criteria for 2014 through 2016 (Column W) is satisfied, therefore, the HU-Beltsville 1-hour SO<sub>2</sub> monitoring data is complete and is acceptable to use in the modeling.

One direction sector that is unique to the Fort Smallwood site involves winds generally from the east (upwind sector from 70 to 130 degrees), for which the upwind fetch involves approximately 20 kilometers over open water, and then at least 10 additional km of no large SO<sub>2</sub> sources on the eastern shore of the Chesapeake Bay before reaching Fort Smallwood. For this sector only, AECOM will include a sector-dependent background concentration, as described in EPA's September 2014 Clarification Memo<sup>16</sup>. The AERMOD User's Guide Addendum<sup>17</sup> states that such sectors should be 60 degrees or more (a warning will be issued for sectors less than 60 degrees).

AECOM reviewed SO<sub>2</sub> monitoring data at the Horn Point ambient monitor in Dorchester County for when wind directions at the Horn Point anemometer are between 70° and 130° (a visual of this sector is shown in Figure 4-21). A 3-year (2014-2016) 99<sup>th</sup> percentile design value from Horn Point will be used in place of the HU-Beltsville monitoring data for this defined sector. The Horn Point design 3-year design value during this period will be calculated using only hours when winds at this monitor were between 70° and 130°. This yields a preliminary design value of 2.5 ppb. AECOM will use this value (2.5 ppb) for the overwater sector, with the Beltsville monitor hour-of-day/seasonal values used for all other directions.

<sup>15</sup> Available at [http://www.epa.gov/ttn/scram/guidance/clarification/Additional\\_Clarifications\\_AppendixW\\_Hourly-NO2-NAAQS\\_FINAL\\_03-01-2011.pdf](http://www.epa.gov/ttn/scram/guidance/clarification/Additional_Clarifications_AppendixW_Hourly-NO2-NAAQS_FINAL_03-01-2011.pdf).

<sup>16</sup> [http://www3.epa.gov/scram001/guidance/clarification/NO2\\_Clarification\\_Memo-20140930.pdf](http://www3.epa.gov/scram001/guidance/clarification/NO2_Clarification_Memo-20140930.pdf)

<sup>17</sup> [http://www.epa.gov/ttn/scram/models/aermod/aermod\\_userguide.zip](http://www.epa.gov/ttn/scram/models/aermod/aermod_userguide.zip)

The 2014-2016 ambient SO<sub>2</sub> background measurement data were obtained from EPA's Air Quality System Data Mart (AQSDM)<sup>18</sup>.

The final background input file to be read by AERMOD will be hourly. The hourly values will use the 3-year averaged seasonal numbers from HU-Beltsville. For hours when the wind from BWI was between 70° and 130°, the 3-year design value (2.5 ppb) from Horn Point as discussed above will be substituted in for those hours.

## 5. Determination of Critical Emission Values

The critical emission value for a facility is the maximum 1-hour average emission rate that, when combined with background, results in a design concentration that is slightly below the NAAQS. Initial modeling using emission rates reflecting either the current 1-hour emission limits (Wheelabrator) or the equivalent 1-hour average emission rate derived from the projected operations (H.A. Wagner and Brandon Shores) will be performed for this modeling effort. This modeling will follow the procedures noted in Section 4, and the cumulative source impacts at each model receptor will be summed with regional background.

The CEV analysis will be conducted for two emission cases involving Fort Smallwood:

- Brandon Shores and Wagner Unit 3 are assumed to be continuously operating. Note that since Wagner Units 1 and 4 operate less than 5% of the time (and could be considered intermittent sources), their “critical emission value” is zero (not operating mode).
- Brandon Shores is assumed to be operating continuously, but Wagner Unit 3 is not operating.

It is likely that the concentration normalized by emissions is lower for Brandon Shores operating alone (due to reduced downwash effects and merged flues) than for the combination of Brandon Shores and Wagner Unit 3. Therefore, a combined CEV emission rate for the first emission case of both plants operating is likely to be applicable to the second case as well, with some margin under the NAAQS for the second case with the same combined emission rate.

The non-attainment guidance issued by EPA in April 2014<sup>19</sup> allows for the consideration of longer emission averaging times that provide for comparable stringency with the critical emission values that can still be protective of the NAAQS. This analysis approach is discussed further in Section 6.

---

<sup>19</sup> <http://www3.epa.gov/airquality/sulfurdioxide/pdfs/20140423guidance.pdf>

## 6. Determination of SO<sub>2</sub> Emission Limits for the Sources Located in the Baltimore, MD NAA

EPA's April 23, 2014 guidance for resolving SO<sub>2</sub> non-attainment areas acknowledges "that it may be possible in specific cases for states to develop control strategies that account for variability in 1-hour emissions rates through emission limits with averaging times that are longer than 1 hour, using averaging times as long as 30-days, but still provide for attainment of the 2010 1-hour SO<sub>2</sub> NAAQS." EPA's general expectation is that for infrequent periods of hourly emissions above the critical emission value, "these periods would be unlikely to have a significant impact on air quality, insofar as they would be very unlikely to occur repeatedly at the times when the meteorology is conducive for high ambient concentrations of SO<sub>2</sub>. EPA considers this option to be an "appropriate balance between providing a strong assurance that the NAAQS will be attained and maintained, while still acknowledging the necessary variability in source operations and the impairment to source operations that would occur under what could be in some cases an unnecessarily restrictive approach to constraining that variability" (emphasis added). Brandon Shores and Wagner Unit 3 are equipped with and operate with SO<sub>2</sub> emissions control devices. For such sources seeking alternate or longer-term emission limits, EPA's guidance notes that:

"Sources with emission control equipment may be especially prone to periodic occurrences of high emissions, arising on occasions when the control equipment is not operating or operating at reduced efficiency. Therefore, the EPA finds it advisable that longer-term average limits for sources that meet these limits through the use of emission control equipment be subject to supplemental limits that serve to constrain the frequency and/or magnitude of occasions of elevated emissions. Establishment of such supplemental limits as part of a longer-term averaging approach is especially important in cases with significant potential for frequent and/or high magnitude occasions of elevated emissions, including, but not limited to, sources using emissions control equipment."

Brandon Shores Units 1 and 2 are two coal-fired boilers that exhaust through a common stack. As mentioned in Section 3.2, these units operate with a FGD scrubber that inherently alters the plume characteristics from dry to wet. AECOM will reserve the option of employing a new technique, "AERMOIST", to derive effective hourly stack temperatures that account for the effect of the heat of condensation. The technical details of this process are described in submittals to the EPA Appendix W proposal docket and in a peer-reviewed journal article<sup>20</sup>. For these units, process upset conditions that could potentially result in infrequent elevated SO<sub>2</sub> emission spikes (e.g., loss of a spray pump in the flue gas desulphurization module) may be difficult to address within a one-hour period in a manner that restores operations to those that preceded the upset condition. These units are operated in a manner that avoids unplanned or abrupt changes in generating load. Consequently, establishing alternate SO<sub>2</sub> emission limits is appropriate for these sources.

Wagner Units 1 and 4 are fueled by oil, with Unit 1 using natural gas typically outside of the winter season. These units operate in a manner that acts to support Units 2 and 3, typically when demand is higher (hot summer days and cold winter days). Because Wagner Units 1 and 4 will operate less than 5% hours annually on oil, establishing alternate SO<sub>2</sub> emission limits would also be appropriate given their infrequent operating schedule on oil.

Wagner Unit 3 is equipped with a dry sorbent injection (DSI) that reduces SO<sub>2</sub> emissions. During rare system malfunctions of the DSI injection, excess emissions of SO<sub>2</sub> can occur. Additionally, at maximum load, a condition that only occurs occasionally during more extreme electrical demand conditions, SO<sub>2</sub> removal may not be as effective due to lower retention time of the sorbent, so SO<sub>2</sub> emissions may be

<sup>20</sup> See Appendix M at <http://www.regulations.gov/#documentDetail;D=EPA-HQ-OAR-2015-0310-0110>. Also see the journal article: Paine, R., Warren, L.L., Moore, G.E., Source Characterization Refinements for Routine Modeling Applications, Atmospheric Environment (2016), doi: 10.1016/j.atmosenv.2016.01.003.

higher than normal for these hours. Given that these events are rather infrequent, Unit 3 will also pursue alternate SO<sub>2</sub> emission limits to account for these infrequent events.

For H.A. Wagner and Brandon Shores, Talen Energy proposes that attainment with the 1-hour SO<sub>2</sub> NAAQS in the Anne Arundel and Baltimore Counties, MD NAA can be assured via compliance with the use of a 30-day rolling average limit calculated as discussed below.

For the purposes of calculating a 30-day average SO<sub>2</sub> emission limit for Brandon Shores Units 1 and 2 and Wagner Units 3, Talen Energy has elected to follow the procedure included in EPA's non-attainment guidance document, Appendix B. In general, EPA expects that any emission limit with an averaging time longer than 1 hour would need at least a slight downward adjustment to compensate for the loss of stringency inherent in applying a longer-term average limit. The procedure for determining the longer-term emission limit is included in Appendix B of the EPA's April 23, 2014 guidance, and is further discussed below.

## 6.1 Appendix B Approach - Overview

As discussed in EPA's 2014 SO<sub>2</sub> nonattainment guidance document (Appendix B), the effect of infrequent emissions above the Critical Emission Value is outlined below:

"Exceedances of the SO<sub>2</sub> NAAQS occur when emissions from relevant sources are sufficiently high on occasions when the meteorology is conducive for those emissions to cause elevated SO<sub>2</sub> concentrations. An illustrative example would be a case in which a single source has a dominant impact on area concentrations, and the source only causes an exceedance at a particular location with light southwest winds with limited dispersion. In this example, the likelihood of an exceedance at that location will be a function of the likelihood of elevated emissions occurring during times of light southwest winds with limited dispersion. Stated more generally, the likelihood of an exceedance is a function of the likelihood of emissions being high when the meteorology is conducive for the source to cause an exceedance. By extension, the likelihood of a violation is a function of the likelihood of emissions being high on a sufficient number of times with meteorology conducive to having exceedances to have the average of the 99<sup>th</sup> percentile daily maximum values exceed the NAAQS. Viewed another way, the occasions when the meteorology is conducive for the source to cause an exceedance at a particular location are likely to be infrequent, and high concentrations are contingent on both emissions being sufficiently high and the meteorology being sufficiently conducive. The NAAQS itself is based on relatively rare occurrences, being based on the 99<sup>th</sup> percentile of daily maximum concentrations. Nevertheless, the point here is that the occurrence of high emissions will not cause an exceedance if it does not occur when meteorology is conducive to having an exceedance. Furthermore, a source with rare occurrences of high emissions and with much more frequent occurrences of moderate emissions is more likely to have moderate emissions on those occasions with meteorology conducive for exceedances, and the design value for the source may be more prone to reflect the moderate emissions than the high emissions."

EPA's 2014 SO<sub>2</sub> nonattainment guidance document establishes a procedure in Appendix B for showing that a longer-term emission limit (with a downward adjustment factor applied to the CEV based on a projected distribution of emissions) can be protective of the 1-hour SO<sub>2</sub> NAAQS. The discussion on page 25 of this guidance further discusses this approach.

"Appendix B documents analyses that the EPA has conducted to evaluate the extent to which longer term average limits that have been adjusted to have comparable stringency to 1-hour limits at the critical emission value provide for attainment. In brief, while a longer term average limit as contemplated here would allow occasions when emissions exceed the critical emission value, the use of a lower limit compensates by requiring most values to be lower than they are required to be with a 1-hour limit at the critical emission value. The EPA expects that a common net result will be that the comparably stringent limit will provide a sufficient constraint on the frequency and magnitude of

occurrences of elevated emissions (especially if supplemented with more direct limits on these occurrences) that a control strategy based on such limits would reasonably provide for attainment.”

Once a 1-hour emission limit (assuming constant operation) at the critical emission value is established based on the traditional modeling approach, the critical emission value could then be used as the baseline for establishing a longer-term averaged emission limit. Historical emissions can be analyzed to determine a representative future emission scenario and then scaled as needed to fit the long-term average emission limit. A source could be expected to experience occasional hourly emission rates greater than the long-term (30-day) average emission limit with the likelihood that such infrequent emissions do not result in a NAAQS exceedance, as discussed above.

In their Appendix B of the 2014 SO<sub>2</sub> nonattainment guidance, EPA has outlined a procedure to conduct modeling of a highly variable source as well as a site-specific modeling approach for demonstrating through a large number of modeling runs that a specific emissions distribution can be shown to protect the 1-hour SO<sub>2</sub> NAAQS. This “Randomly Reassigned Emissions” (RRE) procedure is discussed further below, followed by a discussion as to how this procedure will be applied for this modeling application.

## 6.2 Randomly Reassigned Emissions Approach for Fort Smallwood Sources

The procedures outlined in Appendices B and C of the April 23, 2014 Guidance for 1-hour SO<sub>2</sub> Nonattainment Area SIP Submission Memorandum discuss how to calculate a long-term (30-day) emission limit based upon probabilistic modeling that shows that the longer-term emission rate will still result in 1-hour SO<sub>2</sub> NAAQS compliance. Establishing a 30-day average limit, is most appropriate if the frequency and magnitude of occasionally elevated emissions (above the CEV) will be relatively low (typically no more than 5% of the time). EPA’s Appendix B procedure for determining a suitable longer-term average limit consists of the following steps for a variable emission source.

1. Conduct dispersion modeling to determine 1-hour CEV based on a level of emissions that shows NAAQS compliance; this emission rate is lower than the emission rate of infrequent elevated emission hours (that could occur up to 5% of the year).
2. Derive an estimate of the distribution of future emission from statistical analysis of a set of representative recent emissions data (i.e., CEMS) that reflects the emissions variability that the source is expected to exhibit in the future, once the SIP is implemented, in 2021. This emission distribution can be expressed as a cumulative frequency distribution and can also be expressed as a set of discrete emission “bins” that approximate (or that provide a slightly higher set of emissions than) the cumulative emissions curve. The distribution will include “normal” emission levels at or below the CEV ( $\geq 95\%$  of hours) and the high emission events above the CEV ( $\leq 5\%$  of hours).
3. As needed, adjust the future emission values within the distribution so that all of the sets of modeling runs (using 5 years of meteorological data) described below show NAAQS compliance. This could be an iterative process.
4. In the case of H.A. Wagner and Brandon Shores sources, establish an emissions “rule” that accommodates the high emission events based on the projected distribution of emissions (e.g., some high emission events are expected to occur only during the winter or summer months, corresponding to high load demand). The high emission rates are accommodated in discrete emission “events” that last from 1 to several hours that match the actual emissions behavior.
5. Create a large number (100) of emission data sets (full years of hourly emissions data that reflect the entire emissions distribution) by randomly assigning hourly emission values from the emissions bins throughout the year accounting for the high emission event “rules”.

6. Conduct 100 sets of AERMOD simulation runs (with a 5-year meteorological data set in this case) using the 100 randomly generated emissions data sets from above to obtain the average 99<sup>th</sup> percentile of daily maximum concentrations. Create a 5-year average of the 99<sup>th</sup> percentile statistic at each receptor in preparation for the next step.
7. Compare the modeled design concentration obtained from the 100 model simulations (5-year averages) to the 1-hour SO<sub>2</sub> NAAQS. A successful outcome is that all of the 100 model simulations (5-year averages) show NAAQS compliance.
8. The 30-day rolling average permit limit, which may be seasonally varied, would be consistent with the modeled monthly emission rates in the RRE modeling. This limit will be below the CEV and, as demonstrated by the rigorous modeling, will be adequately protective of the NAAQS.
9. For sources that operate infrequently (< 5% of hours), the CEV will be equal to zero. In these situations, a limit on the number of operating hours will be targeted along with a maximum (not to exceed) 1-hour emission peak rate.

This analysis will first be done with 100 emissions data sets for all sources operating (including the infrequent Wagner 1 and 4 operations) to determine the rolling 30-day average emission rate limits applicable when Brandon Shores and Wagner 3 are operating at the same time (i.e., both must be limited to attain the NAAQS). Then, a second case for which Wagner 3 is not emitting (but still with infrequent Wagner 1 and 4 operations) will be tested, for which the CEV and 30-day average emissions assigned to Wagner 3 are added to the Brandon Shores values from the “all sources” case. This case is expected to result in a larger margin of NAAQS compliance because of reduced building downwash effects for Brandon Shores. In other words, a pound of SO<sub>2</sub> emitted from Wagner 3 has a greater impact than a pound of SO<sub>2</sub> from Brandon Shores; therefore, two pounds released from Brandon Shores will have a lower impact than when one pound is emitted from Wagner 3 and one pound is emitted from Brandon Shores. These analyses for 1) both Brandon Shores and Wagner 3 in operation and 2) only Brandon Shores in operation will result in a combination of two limits applicable in parallel (at all times) that would be protective of the NAAQS: one for Wagner 3 based on its emissions in the first scenario and one for the combination of Wagner 3 and Brandon Shores based on the sum of their emissions in the first scenario. This arrangement covers any combination between the two scenarios (e.g., Wagner 3 and Brandon Shores operating together and Brandon Shores operating without Wagner 3).

A detailed explanation will be provided in the final SIP modeling demonstration report discussing the conditions that limit the emissions variability. This would include the following:

- Years selected for “representative recent emissions data”
- Process changes from baseline emission conditions, meaning changes from the “representative recent emissions data” conditions
- Resulting emissions data set with representative emissions bins
- Any unit limitations in operating hours
- Any limits to the joint operation of units for any given hour
- Any variation from the baseline, in the average percent of time each of the units operates
- Any variation from the baseline, in the average percent of time the units operate together.

### 6.3 Load-Varying Temperature and Velocity for Randomly Reassigned Emission Sources

To ensure that appropriate gas exhaust parameters (temperature and velocity) will be accounted for in the Randomly Reassigned Emissions modeling for varying emission loads, representative values will be calculated based on historical data for Brandon Shores and Wagner sources. Since Wagner Units 1 and 4 will be burning oil, the temperature and velocities will be relatively constant. As a result, full-load parameters will be used across all emission rates for the Randomly Reassigned Emissions modeling.

For Brandon Shores Units 1 and 2, the gas exit temperature is relatively constant across operating loads, as shown in Figure 6-1. Therefore, a median temperature from 2014-2016 data of 323 Kelvin will be used for all emissions bins.

The velocity exhaust parameter for Brandon Shores Units 1 and 2 does vary with operating load. The 2014-2016 hourly data for the combined units will be divided into bins of 200 lb/hr of SO<sub>2</sub> emission rates. The median velocity corresponding to each 200 lb/hr emission bin will be analyzed to determine if there are discrete groups that exist. Table 6-1 summarizes the median velocities for each 200 lb/hr bin. There appears to be 3 distinct groups that the velocities can be assigned to an operating load (minimum, mid and full). For emissions between 1,000 lb/hr and 1,399 lb/hr, a median velocity of 12.42 m/s would be used, corresponding to minimum operating load. For emissions between 1,400 lb/hr and 2,799 lb/hr, a median velocity of 13.63 m/s would be used for mid-load. For full load, emissions greater than 2,800 would be modeled with a velocity of 14.41 m/s.

Since SO<sub>2</sub> emissions are likely to be reduced by approximately 50% due to changes in operations for Wagner 3 (compliance coal and increased use of DSI), obtaining representative gas temperatures and velocities is not as straightforward compared to Brandon Shores. We propose using the ratio between the maximum actual SO<sub>2</sub> hourly emission rate and the future normal operation maximum hourly emission rate (i.e., CEV). Then, we will apply this ratio to the actual emissions over the 2014-2016 period to obtain an adjusted SO<sub>2</sub> hourly emission rate that accounts for compliance coal and 30% DSI efficiency. Figures 6-2 and 6-3 show temperature versus adjusted emission rate and velocity versus adjusted emission rate, respectively. A temperature or velocity value would be assigned to a randomly reassigned emission rate bin based upon where the intersection of that emission rate meets the temperature or velocity data. To be conservative, we would select a temperature and velocity value that conservatively resides on the low end for a given randomly reassigned emission rate. For example, an emission rate of 1,500 lb/hr would yield a temperature of 394.44 K and a velocity of 24.107 m/s.

**Figure 6-1: Brandon Shores Combined Units 1 and 2 Exit Temperatures Versus SO<sub>2</sub> Emissions for 2014-2016**

**Table 6-1: Brandon Shores Combined Units 1 and 2 Median Velocities for Range of Emissions for 2014-2016**

Operating Load	Value	Bin 1	Bin 2	Bin 3	Bin 4	Bin 5	Bin 6	Bin 7	Bin 8	Average of the Velocities Per Operating Load (m/s)
Minimum	Lower Emission (lb/hr)	1000	1200							12.42
	Upper Emission (lb/hr)	1200	1400							
	Median Velocity (m/s)	12.18	12.665							
Mid	Lower Emission (lb/hr)	1400	1600	1800	2000	2200	2400	2600		13.63
	Upper Emission (lb/hr)	1600	1800	2000	2200	2400	2600	2800		
	Median Velocity (m/s)	13.326	13.549	13.506	13.713	13.707	13.73049	13.8865		
Full	Lower Emission (lb/hr)	2800	3000	3200	3400	3600	3800	4000	4200	14.41
	Upper Emission (lb/hr)	3000	3200	3400	3600	3800	4000	4200	4400	
	Median Velocity (m/s)	14.354	14.544	14.761	14.163	14.044	14.235	14.4925	14.685	

**Figure 6-2: Wagner Unit 3 Exit Temperatures Versus Future SO<sub>2</sub> Emissions for 2014-2016**

**Figure 6-3: Wagner Unit 3 Exit Velocity Versus Future SO<sub>2</sub> Emissions for 2014-2016**

## 7. Results of SO<sub>2</sub> NAAQS Compliance Modeling Analysis

A report will be provided that summarizes the procedures followed, the emissions modeled (including CEVS and Appendix B emission data sets) and modeling results including tables and figures. A modeling archive will be provided electronically to MDE.

Areas with elevated concentrations will be reviewed and additional receptors will be modeled if the receptors spacing needs to be refined to an x-y resolution of 100 meters. The modeling results of this SO<sub>2</sub> characterization will be used to determine the future emission limits that will comply with the NAAQS as part of the requirement of the SIP demonstration. The 100 AERMOD simulations using randomly reassigned 1-hour emission rates for Brandon Shores and H.A. Wagner sources will be run with a constant CEV 1-hour emission rate for C.P. Crane and Wheelabrator for the receptors described in this protocol in the Anne Arundel and Baltimore Counties, MD NAA, plus regional background (HU-Beltsville and Horn Point monitors for 2014-2016 as discussed in Section 4.7). The modeling results will indicate that the 5-year average of the 99<sup>th</sup> percentile peak daily 1-hour maximum concentration is below the NAAQS (196.5 µg/m<sup>3</sup>) for each of the 100 AERMOD RRE simulations (done for both Brandon Shores and Wagner 3 operating as well as only Brandon Shores operating). In this case, with the projected emissions as modeled being the basis for new emission limits, the current Anne Arundel and Baltimore Counties, MD NAA can be recommended for a future designation of attainment.

After the modeling is conducted, a table will be provided with the permitted emission rates consistent with the modeling and Appendix B of the SO<sub>2</sub> guidance. The specified emission limits will consist of:

- A rolling 30-day SO<sub>2</sub> emission rate for Wagner 3 that may vary seasonally;
- A total rolling 30-day SO<sub>2</sub> average emission rate for the sum of Brandon Shores and Wagner 3 that may vary seasonally;
- For each stack modeled, the number of hours per year that the CEV emission rate can be exceeded; and
- For each stack modeled, the peak emission rate allowed.

This combination of long-term and short-term emission limits will act to limit the frequency of elevated emissions while providing the modeled facilities with additional operational flexibility, and ensure attainment of the SO<sub>2</sub> NAAQS in Anne Arundel and Baltimore Counties.

## Appendix C-7 Weight of Evidence

### Maryland Department of the Environment

#### Supplemental Information on Air Dispersion Modeling

##### *For State of Maryland 1-Hour SO<sub>2</sub> NAAQS State Implementation Plan for the Anne Arundel County and Baltimore County, MD (“Wagner”) Nonattainment Area*

November 2019

Since the February 2018 submittal of the original SO<sub>2</sub> nonattainment area modeling report, many components of the air dispersion modeling analysis have changed. Of particular importance is that the AERMOD modeling system has gone through two version updates. The ambient background concentrations of SO<sub>2</sub> in the region have seen a decrease of more than 50% as well. As a result, MDE decided to update the original air dispersion modeling analysis for the Case 1 CEV run, which was used to determine the critical emissions value. This Appendix provides detailed information on the parameters that have been updated and the results from the new model runs.

#### **1. Ambient Background Data**

The February 2018 modeling analysis used monitored background concentrations for the years of 2014 – 2016 from the HU-Beltsville monitor (AQS #24-033-0030), combined with data from the Horn Point monitor (AQS #24-019-0004) when wind directions are between 70° and 130° (easterly).

MDE reviewed the monitored background concentrations from the HU-Beltsville and Horn Point monitors with data from years 2016 – 2018. Significant decreases in the monitored concentrations were noted. Table 1 shows the decrease of design values for 1-hour SO<sub>2</sub> NAAQS at these two monitors.

Table 1: 1-Hour SO<sub>2</sub> NAAQS Design Values at HU-Beltsville and Horn Point Monitors

Year	SO <sub>2</sub> 1-Hour NAAQS Design Value (ppb) at HU-Beltsville	SO <sub>2</sub> 1-Hour NAAQS Design Value (ppb) at Horn Point
2014 – 2016	9	6
2015 – 2017	6	4
2016 – 2018	4	3

Source: EPA 2018 Design Value Reports, <https://www.epa.gov/air-trends/air-quality-design-values#report>

The decreasing trend of monitored SO<sub>2</sub> concentrations can also be seen in Figure 1.

Figure 1: Design Value Trends for SO<sub>2</sub> 1-hour NAAQS at the HU-Beltsville and Horn Point Monitors

Consistent with the previous modeling analysis, MDE used varying background values from the most recent 3-year period of 2016 – 2018, whereby the background values vary by season and by hour-of-day. The 2016 – 2018 ambient SO<sub>2</sub> background data were obtained from EPA’s Air Quality System (AQS) Data Mart for the HU-Beltsville monitor. Procedures in EPA’s March 2011 clarification memo<sup>1</sup> with regard to 1-hour SO<sub>2</sub> background values were examined and followed. The HU-Beltsville 1-hour SO<sub>2</sub> monitoring data is sufficiently complete and is acceptable to use in the modeling. The hourly values were averaged for the 3-year period for each season. The AERMOD modeling system defines seasons as following:

- Winter: December, January, February
- Spring: March, April, May
- Summer: June, July, August
- Fall: September, October, November

<sup>1</sup> [https://www3.epa.gov/scram001/guidance/clarification/Additional\\_Clarifications\\_AppendixW\\_Hourly-NO2-NAAQS\\_FINAL\\_03-01-2011.pdf](https://www3.epa.gov/scram001/guidance/clarification/Additional_Clarifications_AppendixW_Hourly-NO2-NAAQS_FINAL_03-01-2011.pdf)

These averaged hourly values were applied to each hour of the 5-year modeling period. The model then added the background concentrations to the predicted SO<sub>2</sub> concentrations for each hour.

The background concentrations used in the modeling analysis are listed in Table 2. The concentrations range from 0.52 µg/m<sup>3</sup> to 6.90 µg/m<sup>3</sup>, compared to a range of 1.31 µg/m<sup>3</sup> to 13.62 µg/m<sup>3</sup> used in the February 2018 modeling analysis.

Table 2: 3-Year Averaged 1-Hour SO<sub>2</sub> Background Concentrations for HU-Beltsville Monitor

Hour	2016 – 2018 Averaged Hourly Values for Winter (µg/m <sup>3</sup> )	2016 – 2018 Averaged Hourly Values for Spring (µg/m <sup>3</sup> )	2016 – 2018 Averaged Hourly Values for Summer (µg/m <sup>3</sup> )	2016 – 2018 Averaged Hourly Values for Fall (µg/m <sup>3</sup> )
1	3.58	1.66	0.87	0.79
2	3.49	1.57	1.05	1.05
3	4.10	1.22	0.52	1.22
4	3.32	1.14	0.61	1.05
5	3.23	1.40	0.79	0.70
6	3.06	1.14	0.79	0.61
7	3.84	1.40	1.40	0.70
8	3.32	3.23	2.27	1.83
9	4.72	4.45	3.41	4.19
10	6.46	4.45	4.54	4.54
11	6.55	4.98	6.11	6.90
12	6.90	5.68	4.63	3.67
13	6.81	4.80	2.36	3.84
14	6.20	5.33	2.71	4.10
15	5.68	4.02	4.10	5.68
16	5.41	4.10	4.28	3.76
17	4.54	3.84	1.92	2.62
18	4.28	3.58	1.75	1.57
19	4.19	2.53	1.14	1.31
20	4.19	1.92	1.40	1.22
21	4.63	2.01	0.79	0.87
22	4.37	1.92	0.61	0.79
23	4.80	1.66	0.96	0.70
24	4.28	1.57	0.96	0.70

A plot of the hourly background values by season and hour is shown in Figure 2.

Figure 2: 2016 – 2018 Averaged SO<sub>2</sub> Background Concentrations Varying by Season and Hour-of-Day

Figure 2 also includes, for reference only, the uniform background values for the Horn Point monitor. The February 2018 modeling analysis used a 3-year (2014 – 2016) 99<sup>th</sup> percentile value from Horn Point (2.5 ppb, or 6.55 µg/m<sup>3</sup>, shown as the black dashed line in Figure 2) in place of the HU-Beltsville monitoring data for when wind directions are between 70° and 130° (easterly).

Unlike the previous modeling analysis, MDE decided to not substitute HU-Beltsville monitor's data with Horn Point monitor's data. All background concentrations come from the HU-Beltsville monitor. MDE analyzed the 1-hour SO<sub>2</sub> data from Horn Point for 2016 – 2018 and determined the 99<sup>th</sup> percentile design value for the specific wind sector to be 0.9 ppb, or 2.35 µg/m<sup>3</sup>, shown as the green dashed line in Figure 2. With most of the predicted high ground level concentrations occurring during the day, it is a conservative measure to use the HU-Beltsville data, not the uniform background data from Horn Point.

#### Measured Ambient Concentrations of SO<sub>2</sub> at Riviera Beach

On January 12, 2018, a source-oriented SO<sub>2</sub> monitor was established at Riviera Beach Elementary School as a Special Purpose Monitor for the purpose of better evaluating actual ambient SO<sub>2</sub> concentrations in the area. This monitor is situated on the Riviera Beach Elementary School property, approximately 2.5

kilometers (1.6 miles) to the southeast of H.A. Wagner Generating Station. Since it began collecting data in January 2018, the measured 1-hour SO<sub>2</sub> concentrations have never exceeded or come close to the 1-hour SO<sub>2</sub> NAAQS of 75 ppb. The maximum daily 1-hour SO<sub>2</sub> concentrations for 2018 and 2019 measured at Riviera Beach monitor is presented in Figure 3.

Figure 3: Maximum Daily 1-hour SO<sub>2</sub> Concentrations at the Riviera Beach Monitor

## 2. Model Version Selection

Model and Preprocessors/ Other Input Data	February 2018 Modeling Model Version No./ Years of Data Used	Most Recent Modeling Model Version No./ Years of Data Used
AERMOD	16216r	19191
AERMET	16216	18081*
AERMINUTE	15272	15272
AERSURFACE	13016	13016
AERMAP	11103	11103**
BPIP-PRIME	04274	04274
Background Concentration Years	2014 – 2016	2016 – 2018
Met Data Years	2012 – 2016	2012 – 2016

All components of the AERMOD modeling system that MDE used in its analysis are the current version, with the exception of AERMET and AERMAP.

- \* - According to the Model Change Bulletin #9 – Version Date 19191 for AERMET, there were no formulation changes or enhancements made to the model for this current version. The five bug fixes made in this version are not believed to cause any significant differences in model outputs from using the previous version of 18081.
- \*\* - According to the Model Change Bulletin #4 – Version Date 18081 for AERMAP, one bug fix and one enhancement were made in this current version. However, these changes are not believed to cause any significant differences in model outputs from using the previous version of 11103. For consistency purposes, the previously determined receptor elevations were used.

MDE elected to use meteorological data for years 2012 – 2016, same as previous modeling analysis (February 2018) for consistency purposes. These met data were re-processed using AERMET version 18081.

### 3. Model Results

MDE conducted AERMOD runs for Case 1 CEV, with the latest model version 19191, and updated background concentrations from 2016 - 2018. The model results are discussed below.

By specifying the MAXDCONT option in AERMOD, the model can output contributions of each source group for given receptors and ranked values.

A comparison of the contributions from each source group between the previous modeling analysis (February 2018) and this modeling analysis is presented in Table 3.

Table 3: Comparison of Source Contributions

	February 2018 Modeling Analysis *	Most Recent Modeling Analysis
Source	Concentration ( $\mu\text{g}/\text{m}^3$ )	Concentration ( $\mu\text{g}/\text{m}^3$ )
Crane Unit 1 & 2	0.61	0.82
Brandon Shores Merged Stack	85.64	85.86
Wagner Unit 1	0.00	0.00
Wagner Unit 3	102.70	102.34
Wagner Unit 4	0.00	0.00
Wheelabrator	0.17	0.24
Ambient Background	7.28	3.77
Peak Impact (Total)	196.40	193.04

\* Source: Table 5-2, *SO<sub>2</sub> Characterization Modeling Protocol Compliance Modeling Report for the Anne Arundel and Baltimore Counties, MD Non-Attainment Area – Rev 1, February 2018*

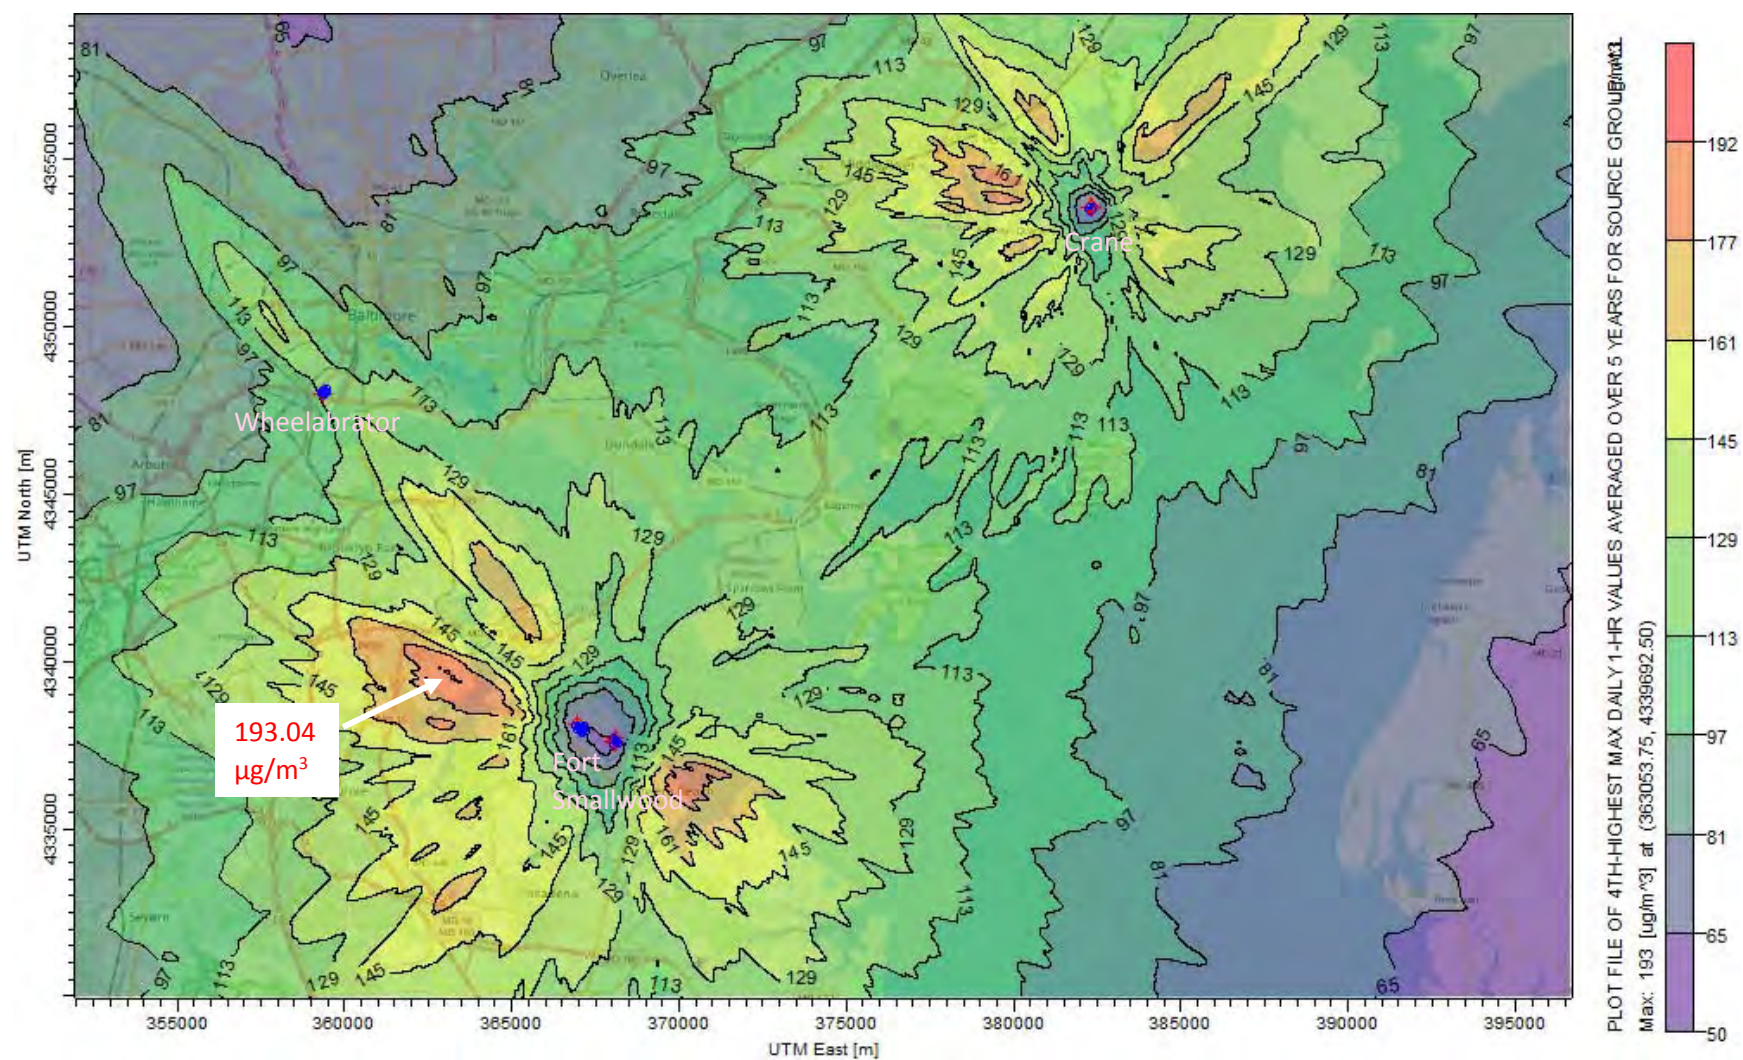

As shown in Table 3, the ambient background at this particular receptor decreased by  $3.51 \mu\text{g}/\text{m}^3$ , from  $7.28 \mu\text{g}/\text{m}^3$  to  $3.77 \mu\text{g}/\text{m}^3$ . The peak impact decreased by  $3.36 \mu\text{g}/\text{m}^3$ , from  $196.40 \mu\text{g}/\text{m}^3$  to  $193.04 \mu\text{g}/\text{m}^3$ .

Figure 4 shows the 1-hour SO<sub>2</sub> isopleth. The peak impact of  $193.04 \mu\text{g}/\text{m}^3$  occurred at the same receptor as in the previous modeling analysis, approximately 4 km (2.5 miles) west-northwest of the Fort Smallwood Complex.

### 4. Conclusions

Based on the analysis performed and highlighted in this Appendix, it can be safely concluded that, modeling analysis using the most recent version of the AERMOD model would not increase modeled ground level concentration for the Case 1 CEV run. Moreover, because the ambient background concentrations in the region have decreased significantly, when combining the updated background data to model predicted ground level concentrations, the peak 1-hour SO<sub>2</sub> impact of  $193.04 \mu\text{g}/\text{m}^3$  decreased from the previous value of  $196.40 \mu\text{g}/\text{m}^3$ . The predicted 1-hour SO<sub>2</sub> concentration for the Case 1 CEV run demonstrates compliance with the 1-hour SO<sub>2</sub> NAAQS.

Figure 4: 1-hour SO<sub>2</sub> Isopleths Showing the 99<sup>th</sup> Percentile Peak Impacts for CEV Case 1

## **Appendix D: EPA's Data Requirements Rule**

EPA's Data Requirements Rule for the 2010, 1-Hour SO<sub>2</sub> Standard

... pages 2144-2180

## ENVIRONMENTAL PROTECTION AGENCY

RIN 2060-AR19

### Data Requirements Rule for the 2010 1-Hour Sulfur Dioxide (SO<sub>2</sub>) Primary National Ambient Air Quality Standard (NAAQS)

**AGENCY:** Environmental Protection Agency (EPA).

**ACTION:** Final rule.

**SUMMARY:** The Environmental Protection Agency (EPA) is promulgating a rule directing state and tribal air agencies (air agencies) to provide data to characterize current air quality in areas with large sources of sulfur dioxide (SO<sub>2</sub>) emissions to identify maximum 1-hour SO<sub>2</sub> concentrations in ambient air. The final rule establishes minimum criteria for identifying the emissions sources and associated areas for which air agencies are required to characterize SO<sub>2</sub> air quality. Air agencies remain free to also characterize air quality in additional areas beyond those required to be characterized under the rule. The final rule also sets forth a process and timetables by which air agencies must characterize air quality through ambient monitoring and/or air quality modeling techniques and submit such data to the EPA. The EPA has issued separate non-binding draft technical assistance documents recommending how air agencies should conduct such monitoring or modeling. The air quality data developed by air agencies pursuant to this rule may be used by the EPA in future actions to evaluate areas' air quality under the 2010 1-hour SO<sub>2</sub> National Ambient Air Quality Standard (NAAQS), including area designations and redesignations, as appropriate.

**DATES:** This final rule is effective on September 21, 2015.

**ADDRESSES:** The EPA has established a docket for this action under Docket ID No. EPA-HQ-OAR-2013-0711. All documents in the docket are listed on the <http://www.regulations.gov> Web site. Although listed in the index, some information is not publicly available, *i.e.*, confidential business information or other information whose disclosure is restricted by statute. Certain other material, such as copyrighted material, will be publicly available only in hard copy. Publicly available docket materials are available either electronically in <http://www.regulations.gov> or in hard copy at

the Docket ID No. EPA-HQ-OAR-2013-0711, EPA/DC, William Jefferson Clinton West Building, Room 3334, 1301 Constitution Avenue NW., Washington, DC. The Public Reading Room is open from 8:30 a.m. to 4:30 p.m., Monday through Friday, excluding legal holidays. The telephone number for the Public Reading Room is (202) 566-1744 and the telephone number for the Air and Radiation Docket Information Center is (202) 566-1742. For additional information about the EPA's public docket, visit the EPA Docket Center homepage at: <http://www.epa.gov/epahome/dockets.htm>.

**FOR FURTHER INFORMATION CONTACT:** For further general information on this rulemaking, contact Dr. Larry D. Wallace, Office of Air Quality Planning and Standards, U.S. Environmental Protection Agency, by phone at (919) 541-0906, or by email at [wallace.larry@epa.gov](mailto:wallace.larry@epa.gov); or Mr. Rich Damberg, Office of Air Quality Planning and Standards, U.S. Environmental Protection Agency, by phone at (919) 541-5592, or by email at [damberg.rich@epa.gov](mailto:damberg.rich@epa.gov).

#### SUPPLEMENTARY INFORMATION:

##### I. General Information

###### A. Does this action apply to me?

Entities potentially affected directly by this final rulemaking include state, local and tribal governments. Entities potentially affected indirectly by this final rulemaking, depending on how state, local and tribal agencies choose to regulate such entities in the future, include owners and operators of sources of SO<sub>2</sub> emissions (such as coal-fired power plants, refineries, smelters, pulp and paper related facilities, waste incinerators, chemical manufacturers and facilities with industrial boilers for power generation) that contribute to ambient SO<sub>2</sub> concentrations, as well as people whose air quality is affected by these facilities.

###### B. Where can I get a copy of this document and other related information?

In addition to being available in the docket, an electronic copy of this document will be posted at: <http://www.epa.gov/air/sulfurdioxide/implement.html>. Upon its publication in the **Federal Register**, only the published version may be considered the final official version of the notice, and will govern in the case of any discrepancies between the **Federal Register** published version and any other version.

###### C. How is this document organized?

The information presented in this document is organized as follows:

##### II. Background for Final Rulemaking

On May 13, 2014, the EPA proposed the Data Requirements Rule (DRR) for the 2010 1-hour SO<sub>2</sub> Primary NAAQS. The preamble to the proposal provided a discussion of the events that led to the EPA's proposal of a new regulation to direct state, tribal and local agencies<sup>1</sup> to better characterize ambient air SO<sub>2</sub> concentrations near large polluting sources. See 79 FR 27447, May 13, 2014. This discussion addressed the adoption of the 2010 SO<sub>2</sub> NAAQS and the suggested implementation approach described in the preamble of that rulemaking; the area designations process under section 107 of the Clean Air Act (CAA); the history of

<sup>1</sup> The final rule applies to air agencies in all states. The definition of "state" in section 302(d) of the Clean Air Act (CAA or Act) means a state, the District of Columbia, the Commonwealth of Puerto Rico, the Virgin Islands, Guam, and American Samoa and includes the Commonwealth of the Northern Mariana Islands.

designations for prior SO<sub>2</sub> NAAQS, including the use of air quality modeling information; the Agency's subsequent issuance of an implementation white paper in May 2012 and input received from stakeholder groups; and the EPA's February 2013 SO<sub>2</sub> NAAQS implementation and designations strategy paper, developed in response to feedback received through this outreach process.<sup>2</sup> This final rulemaking notice does not repeat all of that discussion, but refers interested readers to the preamble of the proposed rule for this informative background.

The proposed rule noted that although the current SO<sub>2</sub> ambient monitoring network included more than 400 monitors nationwide, the scope of the network had certain limitations, and approximately two-thirds of the monitors are not located to characterize maximum 1-hour SO<sub>2</sub> concentration impacts from emissions sources. To more effectively assess potential public health impacts from exposure to high SO<sub>2</sub> concentrations, the proposed rule presented options for requiring air agencies to characterize air quality in the vicinity of large sources of SO<sub>2</sub> emissions that exceed specified annual emissions thresholds. The EPA's proposed preferred emissions threshold option specified that air agencies would be required to characterize air quality in the vicinity of sources that emit over 1,000 tons of SO<sub>2</sub> per year and are located in more highly populated areas (*i.e.*, Core-Based Statistical Areas (CBSA) with population of at least 1 million), and in the vicinity of sources that emit over 2,000 tons of SO<sub>2</sub> per year and are located outside metropolitan areas of at least 1 million population. The EPA also identified two other emission threshold options and requested public comment on these potential emission thresholds values, a CBSA population threshold of 1 million, the combination of emissions and population thresholds as a means of determining how SO<sub>2</sub> sources would be identified, and on any possible alternatives. Under the proposed approach, air agencies, or the EPA, also could require air quality characterization around other sources, if warranted. *See* 79 FR 27453, May 13, 2014.

Under the proposed rule, air agencies would determine for each emissions source exceeding the threshold whether

air quality characterization for that source would be done either through air quality modeling analysis or by conducting ambient monitoring. Apart from the proposed rule, the EPA issued two draft technical assistance documents (TADs) on modeling and monitoring to assist air agencies with this analytical work. The proposed rule also described a process and timetable by which air agencies would be required to identify sources to be characterized, conduct the relevant analyses and submit such data to the EPA. *See* 79 FR 27456, May 13, 2014.

Specific technical considerations regarding air quality monitoring and modeling were also discussed in the proposed rule, along with options for ongoing verification of the air quality characterization in areas that are not otherwise designated as nonattainment. *See* 79 FR 27460, May 13, 2014. The proposal also discussed incentives for air agencies and sources to work together to establish federally enforceable limits on emissions expeditiously in order to avoid requirements for air quality characterization altogether. We refer readers to the proposed rule for the technical, policy and legal rationale that were presented in support of the proposal, and for a complete discussion of the issues for which the EPA requested public comment. Several supporting memoranda, analyses and data were included in the docket for the proposed action.

The 60-day public comment period for the proposed rule closed on July 14, 2014. In section IV of this preamble, we summarize each key issue from the proposal, briefly summarize major comments received and provide a response, and describe the final policy in the rule, including any changes made to the approaches presented in the proposal. A more detailed response to comments document can be found in the docket for this rulemaking.

### III. Summary of the Final Rule Requirements

This section provides a brief summary of the requirements of the final rule. Further discussion of the basis for these requirements and responses to significant comments are provided in the next section. The EPA believes that the approach set forth in this rule directing air agencies to gather additional data to characterize ambient air in the vicinity of larger SO<sub>2</sub> sources is uniquely suited for implementation of the 1-hour SO<sub>2</sub> NAAQS, and the Agency does not anticipate it to be used for other NAAQS pollutants. The final rule establishes minimum requirements for

air agencies to characterize 1-hour SO<sub>2</sub> air quality concentrations across the country, with an emphasis on doing so in the vicinity of sources that have the largest annual SO<sub>2</sub> emissions. Note that there are already minimum SO<sub>2</sub> ambient monitoring requirements in place that were established when the 1-hour SO<sub>2</sub> NAAQS was adopted. *See* 75 FR 35520, June 22, 2010. The requirements in the present rule supplement those monitoring requirements, which remain in place. As discussed in more detail in the next section, these requirements are intended to establish a flexible yet effective program for characterizing SO<sub>2</sub> air quality in priority areas across the country, given existing funding and resource constraints, and given the particular characteristics of SO<sub>2</sub> air pollution in the affected areas. This final rule also reflects the fact that numerous larger sources of SO<sub>2</sub> across the country have in recent years installed, and are expected to install in the near future, additional control measures that may substantially reduce SO<sub>2</sub> emissions in some cases.

Under this rule, each air agency is required to submit a list to the EPA by January 15, 2016, that identifies all sources within its jurisdiction that have SO<sub>2</sub> emissions that exceeded the 2,000 tons per year (tpy) annual threshold during the most recent year for which emissions data for that source are available, plus any additional sources and their associated areas identified by the air agency or by the EPA as also warranting air quality characterization. (The list is a permanent list of prioritized sources that excludes sources in areas designated as nonattainment before January 2016 and is not altered by designations after January 2016.) The rule requires air quality characterization of the area associated with each listed source, and provides two options for this characterization, namely the use of monitoring or modeling. The final rule also provides a third option, under which air agencies would establish a limit requiring emissions from a listed source to be below the 2,000 tpy threshold, which, with the concurrence of the EPA Regional Administrator, would result in that source and its associated area not being subject to requirements for air quality characterization. The EPA anticipates discussions with air agencies early in 2016 to resolve any questions as to what areas warrant air quality characterization. These discussions are intended to address whether any additional areas (*e.g.*, areas with clusters of sources) warrant air quality

<sup>2</sup> The May 2012 White Paper and high-level summaries of stakeholder meetings are available at: <http://www.epa.gov/oaqps001/sulfurdioxide/Implement.html>. These documents and written comments received from stakeholders are also included in the docket for this rulemaking.

characterization, whether existing monitoring networks might serve to address air quality characterization requirements, and whether any new limits intended by the air agencies negate the need for air quality characterization.

For each source on the list, the air agency will be required to indicate by July 1, 2016, whether it will characterize air quality through ambient monitoring or through air quality modeling or, alternatively, whether it will be subjecting the pertinent source or sources to emission limit(s) that will keep the source(s) below this rule's 2,000 tpy threshold. The option identified by the air agency for each source and its associated area will determine the submittal and timing requirements for the air agency to provide the required information.

If the air agency chooses the first option, ambient monitoring for a source, the air agency must include information about the planned new monitor(s) in the annual monitoring plan that the air agency must submit to the EPA by July 1, 2016; and the air agency must also ensure that the new monitor(s) are operational by January 1, 2017. The required monitors shall be sited and operated either as State and Local Air Monitoring Stations<sup>3</sup> (SLAMS) or in a manner equivalent to SLAMS. In either case, monitors shall be subject to reporting and data certification requirements as prescribed in 40 CFR 58.15 and 58.16 (e.g., quarterly reporting of monitoring data to the Air Quality System, and the annual certification of data by May 1 of the following year), and must satisfy applicable criteria in 40 CFR part 58, appendices A, C, and E.

If the air agency chooses the second option, air quality modeling for a source, it must submit a modeling protocol for each such source to the EPA by July 1, 2016, for review and consultation with the EPA Regional Office. The modeling analyses must then be submitted to the EPA by January 13, 2017.

If the air agency chooses the third option, to provide federally enforceable emissions limitations that limit emissions of an applicable source to less than 2,000 tpy, or to provide documentation that the applicable source has permanently shut down, the air agency must notify the EPA of its decision by July 1, 2016, and provide a

description of the planned emission limitation, including identification of the level of the limitation being planned. Especially in areas with multiple sources, the limit(s) should be sufficiently low as to avert the need for air quality characterization that applies for other listed sources. Therefore, the rule requires the concurrence of the EPA as to whether the limit that the air agency intends will suffice in lieu of conducting air quality characterization. By January 13, 2017, the air agency must provide EPA with documentation demonstrating that the emission limits are federally enforceable, adopted, and require compliance by January 13, 2017, in order for areas containing such sources to avoid the need to characterize ambient SO<sub>2</sub> emissions under the rule. If EPA approval is required to make a limit federally enforceable, the submittal must be sent to the EPA early enough such that the EPA has enough time to complete a rulemaking to make the limit federally enforceable by the January 13, 2017, date.

Section IV.D of this preamble provides a discussion of selected technical considerations related to characterizing air quality, but the rule does not prescribe how an ambient monitoring network around an identified SO<sub>2</sub> source is to be designed, or how air quality modeling must be specifically done to meet the objectives of this rule. As stated in the proposal, the EPA has developed TADs that provide approaches on ambient monitoring and air quality modeling when planning and executing air quality characterization activities, and recommends that air agencies refer to these documents to support their efforts. For example, the TAD for ambient monitoring suggests potential options and recommendations on different analyses and approaches that could be considered to help the air agency site source-oriented SO<sub>2</sub> monitors in locations of expected maximum 1-hour concentrations. The TAD for air quality modeling explains that refined dispersion models are able to characterize SO<sub>2</sub> air quality impacts from the modeled sources across the domain of interest on an hourly basis with a high degree of spatial resolution. It suggests that in order to characterize recent air quality levels around a source, it would be acceptable to use actual hourly emissions data, actual meteorological data and actual stack height information as technical inputs to the modeling analysis. However, it is important to note that, except to require that monitoring be sited and operated in a manner equivalent to SLAMS and to

provide that modeling may be based on actual or allowable emissions, this rule does not promulgate any specific requirements with regard to these analytical approaches, and air agencies are expected to use their best professional judgment, consulting as appropriate with the EPA, in conducting these analyses. Air agencies should also contact their respective EPA Regional Offices regarding any additional issues beyond those addressed in the TADs.

The final rule also includes provisions specifying how characterization requirements for listed sources continue into the future (i.e., ongoing data requirements). For areas where air quality is to be characterized through ambient monitoring, the rule requires the monitoring to be conducted for the calendar years of 2017 through 2019, in order to calculate a valid design value for each area. The rule requires that air agencies (or other parties conducting the monitoring) continue the operation of all existing and new monitors used to meet the requirements of this rule. However, it also provides for the possibility that an air agency may obtain EPA approval to terminate operation of a monitor that was established to meet the requirements of this rule if the air quality values at the monitor are low enough to meet specific criteria. Following commencement of operation of a new monitor, the air agency may seek EPA approval to terminate operation of the monitor pursuant to § 51.1203(c)(3) of this rule, if the monitored design value for the first 3-year period or second 3-year period is no greater than 50 percent of the 1-hour SO<sub>2</sub> NAAQS. After the fourth year following commencement of operation of a new monitor, the air agency may be able to seek approval to shut down the monitor if it meets the criteria specified in existing regulations at 40 CFR 58.14.

For areas that were characterized using air quality modeling, the ongoing data requirement applies only where the modeling was based on actual emissions and where the area has not subsequently received a nonattainment designation. In such cases, the air agency will be required to submit an annual report to the EPA providing updated emissions information and recommending to the EPA whether further modeling is warranted to assess any expected changes in recent air quality. For example, it may be appropriate for the air agency to conduct updated modeling for an area if there have been increases in short term emissions rates, an increase in annual emissions, or changes in facility operations. Where warranted, the air agency shall conduct

<sup>3</sup> The SLAMS network is an air quality surveillance system that consists of a network of monitoring stations designated as SLAMS which measure ambient concentrations of those pollutants for which standards have been established in 40 CFR part 50.

updated modeling to characterize air quality in light of the identified emissions changes and present the results in its annual report to the EPA. Analogous to the monitor shutdown provisions noted earlier, the requirement for the annual emissions assessments for an area originally characterized by modeling may be terminated if the air agency provides a modeling analysis demonstrating that actual emissions in the previous year for SO<sub>2</sub> sources in the area results in a modeled design value that does not exceed 50 percent of the NAAQS at any receptor within the modeling domain. While the annual assessment requirement under this rule would be terminated in such cases, any other EPA requirements to provide data (e.g., for the Air Emission Reporting Rule (AERR)) would not be affected.

The EPA received more than 80 comments on the proposed rule. Taking into consideration the range of comments received, the EPA made a number of revisions that are reflected in the final rule, including the following:

- The source emissions threshold approach was changed to a single 2,000 ton annual SO<sub>2</sub> emissions level, so the final rule does not include thresholds that vary depending on the population of the area.
- Air agencies still need to identify in January 2016 a list of sources in their jurisdiction for which air quality is to be characterized, but they now have until July 2016 to indicate whether, for each source, they plan to use modeling or monitoring to characterize air quality, or to adopt an enforceable emissions limit. (The rule clarifies that this list would not include any source located in an area already designated as nonattainment for the 2010 SO<sub>2</sub> NAAQS.) The approach in the proposal would have required the air agency to indicate its planned approach for each source in January 2016.

- The final rule also includes a set of monitor shutdown provisions that is a hybrid of the options included in the proposed rule and the existing monitor shutdown provisions in 40 CFR part 58. A monitor required under this rule would be eligible for shutdown if it has a design value less than 50 percent of the SO<sub>2</sub> standard during one of the first two 3-year periods of operation. After this point in time, any potential shutdown would need to meet the basic shutdown provisions that apply for SLAMS monitors as described in 40 CFR 58.14.

- The proposal took comment on three potential approaches for ongoing requirements for air agencies to provide modeling or emissions data for areas

that were originally characterized with modeling based on actual emissions data. As noted earlier, the approach in the final rule requires the air agency to provide emissions data to the EPA annually for all sources not designated as nonattainment, and to recommend to the EPA whether an emissions change was substantial enough to warrant updated air quality modeling.

- A number of commenters suggested that an air agency should be able to avoid the air quality characterization requirement for a source if it adopted a federally enforceable requirement limiting annual emissions at the source to less than 2,000 tpy. The final rule now includes such a provision. This type of limit would need to be adopted and in effect by January 2017.

#### IV. Responses to Significant Comments on the Proposed Rule

##### A. The Use of Monitoring and/or Modeling Data

###### 1. Legal Authority To Require States To Submit Data Pursuant to This Rule

###### a. Summary of Proposal

In the proposed rule, the EPA explained that the requirements for the air agency to submit the SO<sub>2</sub> monitoring and modeling data described in § 51.1203 of the proposed rule are appropriate steps needed to understand SO<sub>2</sub> air quality throughout the country, and are consistent with section 110(a)(2)(B), section 110(a)(2)(K) and section 301(a)(1) of the CAA. *See* 79 FR 27457, May 13, 2014.

###### b. Brief Summary of Comments

Some state commenters asserted that the DRR modifies the CAA and imposes new monitoring and modeling obligations on air agencies. One commenter suggested that requiring states to develop monitoring or modeling data in accordance with this proposal modifies the statutory mandate to designate all areas by June 2013 because the EPA intends to use these data for designations. One industry commenter stated it is not appropriate to replace the CAA's statutory directive for designations with extra-statutory provisions like those proposed in the DRR.

Several state and industry commenters stated that the proposed requirements and schedules conflict with requirements that apply to the EPA to timely complete designations under section 107 of the CAA. These commenters stated that the CAA required the EPA to make area designations under the new SO<sub>2</sub> standard no later than June 3, 2013, and

that the EPA failed to comply with that mandatory obligation. Therefore, the commenters claimed, the DRR proposal's discussion of a schedule for issuing designations by December 2020 is beyond the EPA's authority. One state commenter cited *EME Homer City Generation LP v. Env't'l Prot. Agency*, 696 F. 3d 7, 27 (D.C. Cir. 2012) and stated that the DRR cannot stand as proposed because it fails to follow the mandatory timelines for promulgating area designations, and, therefore, exceeds the EPA's statutory authority.

##### c. EPA Response

The comments that assert that the EPA has not designated areas under the 2010 SO<sub>2</sub> NAAQS in a timely manner are beyond the scope of this rulemaking, and are not germane to the issue of the EPA's statutory authority to direct air agencies to conduct monitoring or modeling to further characterize ambient air concentrations of SO<sub>2</sub>. Through this rulemaking, the EPA is not establishing or modifying any area designation requirements provided for in section 107 of the CAA, nor does any aspect of this final rule conflict with any provision of section 107 that directs states and the EPA to take timely action to issue designations. The purpose and effect of this rulemaking is to require air agencies to characterize air quality in priority areas throughout the country where existing ambient monitors may not be adequately characterizing peak 1-hour SO<sub>2</sub> ambient air concentrations. The air quality data obtained as a result of this rulemaking then may be used in future analytical actions by the EPA, including designations of any undesignated areas or redesignations of already designated areas. It is true that in the proposed rule preamble we discussed how the timing of the implementation of this rule would fit with our intended schedule for completing area designations, but the proposal did not itself purport to establish a binding schedule for completing designations.

The EPA notes that litigation was filed against the EPA to compel the Agency to complete designations under CAA section 107, and on March 2, 2015, the court in one of those cases issued a ruling that places the EPA on a binding schedule to complete area designations for the 2010 1-hour SO<sub>2</sub> NAAQS. *See, Sierra Club, et al. v. McCarthy*, Case No. 13-cv-03953-SI (N.D. Cal., March 2, 2015) (Order Granting Joint Motion To Approve And Enter Consent Decree And Denying Other Motions As Moot; and Consent Decree). Copies of the court's order and the March 2015 consent decree setting forth the EPA's schedule

for completing designations have been placed in the docket for this rulemaking. Under the schedule ordered by the court, the EPA is required to complete the designations in no more than three future rounds.

First, by July 2, 2016 (16 months from the date of the court's order), the EPA must sign a notice for publication in the **Federal Register** that promulgates designations for remaining undesignated areas that: (a) Based on air quality monitoring in the three full calendar years preceding that date have monitored violations of the NAAQS; or (b) contain any stationary source that has not by March 2, 2015, been "announced for retirement" and that, according to data in the EPA's Air Markets Database, either (1) emitted more than 16,000 tons of SO<sub>2</sub> in 2012, or (2) emitted more than 2,600 tons of SO<sub>2</sub> and had an annual average emission rate of 0.45 lbs. SO<sub>2</sub>/Mmbtu or higher in 2012. (The March 2015 consent decree defines "announced for retirement" as meaning "any stationary source in the United States with a coal-fired unit that as of January 1, 2010, had a capacity of over five (5) megawatts (MW) and that has announced it will cease burning coal at that unit through a company public announcement, public utilities commission filing, consent decree, public legal settlement, final state or federal permit filing, or other similar means of communication.")

Second, by December 31, 2017, the EPA must sign such a notice promulgating designations for remaining undesignated areas in which, by January 1, 2017, states have not installed and begun operating a new SO<sub>2</sub> monitoring network meeting EPA's specifications referenced in this rulemaking. Finally, by December 31, 2020, the EPA must sign a notice promulgating designations for all remaining undesignated areas.

The EPA notes that the schedule imposed by the court will allow at least the latter two stages of designations to be informed and benefited by the additional information that is timely obtained pursuant to this final rule, as appropriate. However, we also note that the round of designations that is required to be completed by July 2, 2016, will likely be conducted before state air agencies and the EPA will have been able to implement this final rule, and will instead rely upon data and information that is separately developed or obtained during the designations process. Nevertheless, as explained later in this document, depending on how those areas become designated in 2016, the rule may still result in additional

information that could inform future assessments of attainment status for such areas.

The EPA continues to believe that the requirements of this rule for air agencies to submit a list of sources where further air quality characterization is needed, and the other data submittal requirements found in § 51.1203 of this rule, are appropriate steps needed to better understand SO<sub>2</sub> air quality throughout the country, and are consistent with section 110(a)(2)(B), section 110(a)(2)(K), and section 301(a)(1) of the CAA. The commenters did not challenge this view. Section 110(a)(2)(B) indicates that State Implementation Plans (SIPs) are to "provide for establishment and operation of appropriate devices, methods, systems, and procedures necessary to (i) monitor, compile and analyze data on ambient air quality and (ii) upon request, make such data available to the Administrator." Section 110(a)(2)(K) states that SIPs shall "provide for (i) the performance of such air quality modeling as the Administrator may prescribe for the purpose of predicting the effect on ambient air quality of any emissions of any air pollutant for which the Administrator has established a NAAQS, and (ii) the submission, upon request, of data related to such air quality modeling to the Administrator." Section 301(a)(1) provides the EPA with general authority to establish regulations as necessary to carry out the agency's functions, which in this case includes ensuring the attainment of the SO<sub>2</sub> NAAQS throughout each state. This section states that "The Administrator is authorized to prescribe such regulations as are necessary to carry out his functions under this chapter."

The EPA often establishes and revises monitoring requirements for implementing NAAQS. Those requirements will not necessarily always generate new information in time to inform timely area designations under CAA section 107. *See, e.g.*, 75 FR 81126, 81130, December 27, 2010. The validity of such rules does not depend upon whether information generated pursuant to those requirements will be gathered in time to support designations that are timely under section 107. Here, the commenters have raised no objection to the central premise of the rule, which is that additional information that better characterizes air quality near larger sources of SO<sub>2</sub> is warranted and is authorized to be required under sections 110 and 301 of the Act. Irrespective of when the EPA uses this information—for example, irrespective of whether the EPA

promulgates initial designations of "unclassifiable" (and then uses the information collected pursuant to this data requirements rule in later redesignations), or whether the EPA promulgates the remaining designations after the information required here becomes available—the EPA believes that this rule is authorized and is warranted. Therefore, in this final rulemaking, the commenters have provided no basis for the EPA to not require air agencies to submit such SO<sub>2</sub> monitoring and modeling data to the EPA, as proposed. The final rule is fully consistent with the Agency's broad authority under section 110 and 301, as well as with the EPA's authority under CAA section 114(a)(1) to direct any person to provide information as is reasonably required to improve characterization of ambient air quality near larger sources of SO<sub>2</sub>.

## 2. Legal Authority To Base Air Quality Evaluations on Modeling Data

### a. Summary of Proposal

In the proposal, the EPA stated that existing air quality modeling tools are technically sound and historically have been used to characterize SO<sub>2</sub> air quality when monitoring data were not available; therefore, the EPA considers these modeling tools appropriate for assessing air quality impacts from SO<sub>2</sub> emissions. The EPA stated that historical use of modeling to characterize SO<sub>2</sub> air quality concentrations has been affirmed as technically valid and lawful under the CAA by reviewing courts. *See* 79 FR 27448, May 13, 2014.

### b. Brief Summary of Comments

Some industry group commenters stated that the DRR provisions allowing for modeling to characterize ambient SO<sub>2</sub> concentrations go beyond what is necessary to comply with the CAA, arguing that 40 CFR 50.17 provides that monitoring is the sole basis for determining attainment. Commenters stated that the precise wording of 40 CFR 50.17 establishes ambient air monitoring as the only basis for determining if the SO<sub>2</sub> NAAQS is being met because it specifies that:

(a) The level of the national primary 1-hour ambient air quality standard for oxides of sulfur is 75 parts per billion (ppb, which is 1 part in 1,000,000,000), measured in the ambient air as SO<sub>2</sub>.

(b) The 1-hour primary standard is met at an ambient air quality monitoring site when the 3-year average of the annual (99th percentile) of the daily maximum 1-hour average

concentrations is less than or equal to 75 ppb, as determined in accordance with appendix T of this part.

(c) The level of the standard shall be measured by a reference method based on appendix A or A-1 of this part, or by a Federal Equivalent Method (FEM) designated in accordance with part 53 of this chapter.

One public interest group commented that the provisions in the proposed DRR for conducting modeling are consistent with the EPA's historic use of air dispersion modeling for multiple NAAQS implementation purposes. This public interest group stated that dispersion modeling has a lengthy history as an appropriate tool for use in SO<sub>2</sub> designations and other actions, and provided several references to the EPA's documents and to court rulings to demonstrate that historic use.

In contrast, without disputing the fact that the EPA has often relied upon modeling to inform decisions implementing the SO<sub>2</sub> NAAQS, several state and industry commenters stated that monitoring, not modeling, has historically been used for designation of areas as attainment or nonattainment under this and other NAAQS. Several industry commenters supported the EPA's use of notice-and-comment rulemaking through the DRR to address certain major issues, including the use of monitoring and/or modeling to characterize air quality and make remaining area designations.

#### c. EPA Response

This final rule does not make any decisions or determinations regarding whether any area is in fact meeting or not meeting the NAAQS based on either monitoring or modeling information. Those decisions will be made in separate future actions, or have already been made for some areas in prior actions. *See e.g.*, 78 FR 47191, August 5, 2013. Therefore, this final rule does not take final action on the issue of whether it is permissible to implement the commenter's previous quoted provisions of 40 CFR 50.17(a)–(c) based on a combination of both monitoring and modeling information where both are available, or exclusively on modeling information where appropriate modeling information is available and monitoring is not. The commenters' objections appear to focus on how future-gathered information resulting from the rule may or can be used in subsequent NAAQS implementation actions, but the focus of this rule is on the initial gathering of the information itself. In future designation, redesignation, or other implementation actions, commenters may raise their

objections to the validity of information that the EPA relies upon in those specific actions, but such objections are beyond the scope of this final rule.

The commenters appear to be raising objections that were also raised after the EPA's promulgation of the 2010 SO<sub>2</sub> NAAQS, in response to the EPA's final rule preamble discussion explaining the Agency's then-intended implementation approach under the NAAQS. In their petitions for judicial review of the NAAQS, several states claimed that the EPA's discussion of the intended use of modeling in NAAQS implementation contravened the regulatory text of § 50.17. However, noting that the petitioners' claims addressed potential final implementation actions that had not yet in fact occurred, the U.S. Court of Appeals for the D.C. Circuit dismissed the petitioners' claims without addressing their merits, or lack thereof. *See National Environmental Development Association's Clean Air Project v. EPA*, 686 F.3d 803 (D.C. Cir. 2012). Likewise here, the EPA is not yet taking any action to apply modeling regarding any decision of whether an area is or is not meeting the NAAQS.

In any event, we note that although 40 CFR 50.17(a)–(c) very clearly sets forth the criteria for determining whether the NAAQS is met at a monitoring site, it does not by its terms restrict how such decisions may be made more broadly in areas impacted by SO<sub>2</sub> sources, including areas where there are no monitoring sites or where monitors are not sited at the point of maximum ambient concentration. Indeed, it is the relative scarcity of such monitors that has caused the EPA to undertake this rulemaking to enable states and the Agency to better understand just what the ambient air impacts are from larger sources of SO<sub>2</sub>, which may not be captured by the current limited monitoring network. It is true that past area designations processes for most NAAQS (such as for ozone) having violations caused and contributed to by multiple sources over a broad region have relied primarily on air quality monitoring data to identify areas that violate the standard. However, it is important to note, as the EPA explained in the final 2010 SO<sub>2</sub> NAAQS preamble, that there is a long history of also using dispersion modeling information to inform area designations for the SO<sub>2</sub> NAAQS. *See, e.g.*, 75 FR 35551, June 22, 2010.

The EPA and the air quality management community have recognized over many years that peak concentrations of SO<sub>2</sub> are commonly caused by one or a few major point sources in an area, and that peak

concentrations are typically observed relatively close to the source. Many factors influence the observed SO<sub>2</sub> concentrations around emissions sources, including the sulfur content of fuel that is combusted, the sulfur content of material being heated as part of an industrial process, the rate of SO<sub>2</sub> emissions per hour, stack height, topography, meteorology, monitor location and source operating schedule. But because ambient SO<sub>2</sub> concentrations are not the result of complex atmospheric chemical reactions (unlike ozone or PM<sub>2.5</sub>), they can be modeled accurately using well-understood air quality modeling tools, especially in areas where one or only a few sources exist. In the 1970's, when the original SO<sub>2</sub> NAAQS were established, there were significantly more SO<sub>2</sub> monitors in operation nationally than today. Even then, the EPA and air agencies acknowledged the utility of modeling in order to inform area designations under the SO<sub>2</sub> NAAQS. *See e.g.*, 43 FR 45993, October 5, 1978.

#### 3. The Use of Monitoring and/or Modeling for Making Decisions About Air Quality

##### a. Summary of Proposal

In the proposed rule, the EPA explained that the current ambient SO<sub>2</sub> monitoring network, on the whole, is not appropriately positioned, or of adequate size, for purposes of the 2010 SO<sub>2</sub> standard to characterize the air quality around many of the nation's larger SO<sub>2</sub> sources in operation today. The EPA stated that, because ambient SO<sub>2</sub> concentrations are not the result of complex chemical reactions (unlike ozone or PM<sub>2.5</sub>), they can be modeled accurately using well understood air quality modeling tools, especially in areas where one or only a few sources exist. However, the EPA noted that some areas may not be conducive to modeling, and for such areas the EPA encouraged air agencies to consider using enhanced monitoring to characterize air quality. *See* 79 FR 27448, May 13, 2014.

##### b. Brief Summary of Comments

Several state and industry commenters supported the provision in the proposed rule allowing air agencies to have the option to use modeling and/or monitoring to characterize SO<sub>2</sub> ambient air concentrations, as it provides appropriate flexibility for both the states and affected sources. Several commenters supported the EPA's observation that modeling may not be appropriate for all SO<sub>2</sub> evaluation scenarios, and supported the ability of

states to choose to evaluate NAAQS attainment through either dispersion modeling or ambient monitoring. However, several state and industry commenters cautioned that monitoring data should be the primary basis for such decisions, especially designating nonattainment areas. Several commenters claimed that, as modeling is frequently affected by factors such as emissions inputs, meteorological data and local geography, it is not as accurate or reliable as real-time, multiple-year monitoring. Other commenters claimed that modeling is advantageous because it characterizes air quality in all directions around a source with appropriate accuracy and can be done with less expense than ambient monitoring, which only characterizes air quality at a single location. Some industry commenters suggested the text of proposed § 51.1201 be revised to state that monitoring is the EPA's preferred analytical approach under the rule.

#### c. EPA Response

The EPA agrees with commenters who stressed the need to give air agencies the option to characterize SO<sub>2</sub> ambient air quality through either enhanced monitoring or modeling, and the EPA is maintaining that approach in this final rule. The EPA believes that the commenters have not presented any persuasive reasons for changing the basic positions previously discussed in the preamble to the final rule of the 2010 SO<sub>2</sub> NAAQS rulemaking, the February 2013 Strategy Paper, or in the proposed rule for why both air quality modeling and ambient monitoring are appropriate tools for characterizing ambient air quality for purposes of informing future decisions to implement the SO<sub>2</sub> NAAQS. However, as explained earlier, in this final rule the EPA is not taking final action to make any determinations regarding any area's status with respect to attaining or not attaining the NAAQS, but is only prescribing criteria and a process for how and when air agencies are to gather and provide to the EPA additional needed information. How the information is used in subsequent actions evaluating the attainment status of specific areas will depend upon the information that air agencies collect in the future and what it shows about areas' ambient air quality.

#### B. Source Coverage and Emission Threshold Options

##### 1. Summary of Proposal

In the proposal, the EPA recognized that the characterization of air quality in areas around more than 20,000 SO<sub>2</sub>

sources nationally would not be feasible. The proposal stated that the key objective to be achieved by using SO<sub>2</sub> source emission thresholds would be to focus the limited available resources at the state, tribal, local and federal levels toward characterizing air quality in areas having the largest SO<sub>2</sub> emitting sources due to the fact that larger sources can be expected to be the most likely potential contributors to violations of the SO<sub>2</sub> NAAQS. The EPA stated in the proposed rule that, just as NAAQS ambient monitoring networks are designed to measure air quality in areas meeting specific criteria where the public is likely to be exposed and violations may be likely to occur, the SO<sub>2</sub> annual emission threshold options in the rule are designed to meet a similar objective. *See* 79 FR 27453, May 13, 2014.

In considering how to develop effective options for identifying the minimum set of sources around which states would be required to characterize ambient air quality, we considered three important issues and requested comment on each:

- What would be an appropriate emissions metric for identifying sources?
- Should the threshold options require characterization of smaller sources in areas with higher populations?
- What would be an appropriate threshold for identifying sources near which air quality is to be characterized?

The notice of proposed rulemaking also addressed a number of additional elements of the implementation of these thresholds. In the discussion below, the EPA summarizes these additional proposed features, summarizes comments on these proposed features, and describes the EPA's responses. Note that this section is structured so that all the issues related to emissions thresholds are presented together before proceeding to the comment summaries on these issues, and then to the EPA's responses and final decision.

a. Emissions Metric: What would be an appropriate emissions metric for identifying sources?

The proposal presented a discussion about what emissions-related metric would be most appropriate for this rule. The proposal noted that for the 1-hour SO<sub>2</sub> NAAQS, the ideal metric for identifying sources near which air quality is to be characterized would be a 1-hour SO<sub>2</sub> emissions rate. However, the EPA observed that while 1-hour SO<sub>2</sub> emission rate data are available for most electricity generating units (EGUs)

because they operate continuous emission monitors, many non-EGUs do not operate continuous emission monitors on all emission points and produce 1-hour data. For this reason, the proposal stated that the emissions threshold options presented in this rulemaking should be expressed in terms of annual emissions of SO<sub>2</sub> because annual emissions information is readily available for all large SO<sub>2</sub> sources.

The EPA requested comment on the use of annual emissions (*i.e.*, tons of SO<sub>2</sub> per year) as the metric to be used for an emissions and population-based threshold approach, or, alternatively, for a solely emissions-based threshold approach, to identify SO<sub>2</sub> sources around which further ambient air quality characterization with respect to the 1-hour SO<sub>2</sub> NAAQS might be required. The EPA also requested comment on any potential alternative factors that should be considered for defining emissions thresholds, along with any information about the availability of data related to any alternative factor for all SO<sub>2</sub> sources nationally, the time and resources needed to develop a database for this alternative factor, any associated technical analysis and rationale for using these other factors in defining source thresholds. *See* 79 FR 27454, May 13, 2014.

b. Should the threshold options require air quality characterization near smaller sources in areas with higher populations?

In the proposed rule, the proposed emissions threshold option and the other two options on which the EPA requested comment each had a "two-pronged" form. Each potential option was expressed with a higher emissions threshold for identifying sources located outside of CBSAs with a population equal to or greater than 1 million persons, and a lower emissions threshold for identifying sources located within such CBSAs. The reasoning given for this proposed approach was that a lower threshold for urban sources could help increase public health protection because there are more people in an area that could be impacted by relatively smaller sources. The EPA requested comment on its proposed use of the 1 million person CBSA population threshold for representing the population exposure component of the source threshold options in this rule. The EPA also requested comment on whether to include a population exposure-based threshold at all; and on whether alternative, or additional, criteria would

be appropriate to further focus resources on characterizing air quality in areas with a higher likelihood of population exposure. *See* 79 FR 27455, May 13, 2014.

c. What is an appropriate threshold level or levels for identifying sources near which air quality is to be characterized?

The EPA proposed one preferred option and took comments on two additional options. Option 1 (proposed preferred option) would require ambient air quality characterization around any source with annual emissions greater than 1,000 tpy and which is located within a CBSA having 1,000,000 or more persons, and around sources with emissions greater than 2,000 tpy located outside CBSAs having 1,000,000 or more persons. Option 2 would require ambient air quality characterization around sources with emissions greater than 2,000 tpy that are located within any CBSA having 1,000,000 or more persons, and around sources with emissions greater than 5,000 tpy located outside CBSAs having 1,000,000 or more persons. Option 3 would require ambient air quality characterization around sources with emissions greater than 3,000 tpy that are located within any CBSA having 1,000,000 or more persons, and around sources with emissions greater than 10,000 tpy located outside CBSAs having 1,000,000 or more persons.

The EPA requested comment on the preferred option and the other two options described in the proposal. The EPA also requested comment on any possible alternatives that might be appropriate for consideration. The EPA requested comment on the scope of sources for which we would require data. In addition, the EPA also requested any information identifying sources that would be identified by these options but that have confirmed documentation to show that they will shut down in the next several years.

d. Discretion for Air Agencies and the EPA To Address Additional Sources

The EPA noted in the proposed rule that, in addition to meeting the requirements to provide information regarding areas with sources over the future promulgated thresholds, there may still be situations where an air agency would need to characterize air quality for other sources below the thresholds; specifically, where the air agency, or the EPA Regional Administrator, determines that they may have the potential to violate the NAAQS. Application of air quality characterization requirements was noted

to be possibly warranted, for example, where multiple smaller sources located in close proximity may collectively exceed the emissions thresholds and/or cause or contribute to NAAQS exceedances. *See* 79 FR 27455, May 13, 2014.

## 2. Summary of Comments

This section provides a brief summary of comments received on each of the four source threshold issues identified previously, as well as additional features of the EPA's proposed implementation of thresholds.

### a. Comments on an Appropriate Emissions Metric

Most commenters that addressed the emissions metric issue supported using annual SO<sub>2</sub> emissions (in tpy) as the appropriate metric for defining source thresholds. Several commenters stated that it is most appropriate to evaluate annual emissions since these data are widely reported to the EPA and are readily available. Some industry commenters stated that using an annual emissions based threshold approach for identifying areas to be evaluated would serve to make more manageable the demands on state, tribal, local and federal resources. Several other commenters stated that the use of additional factors such as stack height, 1-hour SO<sub>2</sub> emission rate, proximity to sensitive populations, and topography would make the source identification process unnecessarily difficult and time consuming. On the other hand, a few regulatory agency commenters urged the establishment of supplemental criteria based on short-term spikes in emissions.

### b. Comments on Whether the Options Should Require Characterization Near Smaller Sources in Areas With Higher Populations

A number of state and industry commenters supported the application of a lower emission threshold in urban areas. Some commenters stated that population centers represent locations of higher potential public exposure and, therefore, characterization of air quality in these areas would be more representative of the public's SO<sub>2</sub> exposure risk. Several state and industry commenters stated that a threshold approach based purely on emissions could inappropriately focus limited resources on areas with limited to no public exposure. Some state commenters noted that, as a precedent, a population threshold has been used to establish the minimum monitoring requirements for the SO<sub>2</sub> NAAQS as well as the NAAQS for nitrogen dioxide,

carbon monoxide, and particulate matter.

Some commenters stated that many sources located within an existing CBSA are located on the edge of the boundary in less populated areas and urged the EPA to consider more refined census data based on population density. One industry commenter suggested, for example, that the EPA could use population density data around the affected facilities out to a radius of 10 kilometers (km) and, if average population density from the 2010 census in this area exceeds a certain threshold (e.g., 100 persons/square km), then the lower emissions criteria would be used. Some tribal commenters, some environmental group commenters, and some state commenters recommended against applying different thresholds in less populated areas, in order to assure that all areas are equally protected against violations of the air quality standard.

### c. Comments on Source Threshold Options

One public interest group and several states urged the EPA to adopt the proposed Option 1 level of 1,000 tpy, but apply it uniformly, regardless of population in order to ensure a basic level of health protection to people who live around the sources. Some commenters stated that because modeling has shown that sources with emissions below 2,000 tpy have the potential to cause or contribute to modeled NAAQS violations, an emissions threshold of 1,000 tpy is more appropriate to ensure that air quality characterizations are accurately capturing potential NAAQS violations.

Several state and industry commenters supported Option 2 stating it balances limited agency resources for the implementation of this rule while still allowing important SO<sub>2</sub> emission source areas to be evaluated. Some industry commenters stated Option 2 appears to be the best option because the difference between the number of sources captured by Options 1 and 2 is substantial while the difference in overall emissions covered by the two options is small.

Numerous state and industry commenters supported Option 3, stating it would apply reasonable thresholds without burdening states with unnecessary modeling or monitoring. One industry commenter stated that this option would allow states to focus their limited resources on the areas with the largest 211 sources of SO<sub>2</sub> emissions.

One industry commenter stated that if the EPA decides that either Option 1 or 2 is preferable, then the source

threshold needs to be revised to take into account the following additional factors: The distance a source is located from population centers in general and sensitive populations in particular; stack heights; topography and meteorological factors unique to the source(s); and economic conditions that will affect a source's expected SO<sub>2</sub> emissions. This commenter disagreed with the proposal's statement explaining why the Agency does not believe it necessary for air agencies to consider such factors, stating that the lack of a nationwide database with respect to such factors is irrelevant since the modeling is to characterize localized ambient air quality.

#### d. Comments on Discretion To Address Additional Areas

Several state and tribal commenters requested clarification of criteria the EPA would use to determine additional areas to be characterized beyond those with sources emitting more than the applicable threshold. A few commenters offered specific recommendations, for example to characterize areas of 10 km or 25 km diameters in which total emissions exceed the threshold but those of no single source exceeding the threshold. A few commenters recommended that the EPA should not have the discretion to subject additional areas to characterization unless total emissions in the areas exceed the applicable threshold. Some commenters recommended that the rule specify criteria to be used to identify multi-source areas that would need to be characterized. Conversely, some commenters recommended that the EPA not codify any specific criteria, recommending instead that the EPA provide guidance on how it envisions addressing areas with multiple sources and rely on the professional judgment of air agency personnel in consultation with the EPA to identify specific additional areas that warrant being characterized. Also, one state commenter recommended that any area "that, based on the state's knowledge, has the potential to exceed the NAAQS" should become subject to requirements for air quality characterization. Finally, a few industry commenters and a few state commenters urged that the EPA not have the discretion to subject additional areas to DRR requirements.

#### 3. EPA Response

The EPA considered the many and varied comments received on the source threshold options presented in the proposal. After considering the comments received and as explained below, the EPA has decided to establish

a requirement for air agencies to identify all sources with annual SO<sub>2</sub> emissions that exceed 2,000 tpy (using emissions data from the most recent calendar year for which such data are available) and characterize air quality around such sources according to the timeline in section IV.C of this preamble. The following subsections also address the other comments relating to applicability of the requirements for air quality characterization described previously.

##### a. Emissions Metric

The EPA agrees with the many commenters who expressed support for using an annual emissions metric because annual emissions data are most readily available for all large SO<sub>2</sub> sources, whereas 1-hour emissions rate information is not readily available for all SO<sub>2</sub> sources. Since the tpy emissions metric is a common denominator in the emissions inventory and reporting universe, the EPA believes that the use of this metric is most appropriate to be required under a rule that applies broadly to areas with sources that do not already measure 1-hour emissions rates. Using tpy will provide air agencies and the regulated community a common, easily verifiable, straightforward approach for identifying sources around which air agencies are required to characterize air quality. This approach will rely on existing emission inventory collection systems that are already in place. An approach based on tons of emissions per year also should reduce unforeseen or otherwise uneven application of the requirements for air quality characterization that could arise if different metrics are used for different SO<sub>2</sub> source sectors to identify areas for which air agencies are required to characterize air quality.

The EPA acknowledges that some state commenters suggested inclusion of a 1-hour emissions rate-based criterion for identifying certain sources with infrequent, episodic SO<sub>2</sub> emissions at atypically high rates that could impact nearby populations. The EPA notes that the emissions threshold included in the final rule establishes only minimum requirements for identifying sources. The EPA agrees with state commenters who recommended that air agencies should also characterize areas that, based on their knowledge of sources and areas, may be at risk of violating the standard. Thus, under this rule air agencies could also require characterization of air quality near sources prone to episodic emissions with relatively high rates or amounts, as appropriate. However, because short-term emissions data are not available for all SO<sub>2</sub> sources, the EPA did not include

in this rule a minimum requirement for identifying source areas needing air quality characterization based on this metric.

##### b. Characterization Near Smaller Sources in Areas With Higher Populations

The EPA considered the comments received on the issue of whether a lower emissions threshold should be included for areas with more dense populations (e.g., CBSAs greater than 1 million population). A number of commenters appeared to interpret the inclusion of a lower threshold for areas with higher population as being less protective of the public in less populated areas. The EPA wants to clarify that this was not the intention behind the population-inclusive options included in the proposed rule. The SO<sub>2</sub> NAAQS, and all NAAQS, are intended to provide equal protection for citizens throughout the country. The proposed use of both population and emissions thresholds as a means to require air quality characterization was simply one approach to focus limited federal and state modeling and monitoring resources into characterizing locations where a greater coincidence of people and SO<sub>2</sub> emissions occur, and thus a potentially greater potential for exposure is presented. After reviewing the comments on this issue, however, the EPA has decided not to move forward with the proposed preferred approach, and instead to apply requirements for air quality characterization based on emissions levels uniformly across the country for both more urbanized and less urbanized populations so as to focus primarily on the size of the sources.

It should be noted here that any monitoring that occurs pursuant to this rulemaking is potentially in addition to, or can possibly help to satisfy, required SO<sub>2</sub> monitoring stemming from 40 CFR part 58, appendix D, section 4.4. Those monitors required in 40 CFR part 58, appendix D, section 4.4 are determined using a unique metric that accounts for the coincidental occurrences of SO<sub>2</sub> emissions and population, namely the Population Weighted Emissions Index (PWEI). This rulemaking does not supplant or otherwise modify those existing requirements.

##### c. Emissions Threshold

Regarding the comments EPA received expressing preferences on the proposed emission threshold options, the EPA notes the wide range of views. A few commenters recommended alternate thresholds in the range from 1,000 tpy to 10,000 tpy, or

recommended pairs of thresholds within this range. Some commenters provided modeling analyses as an indication that sources larger than 12,000 tpy did not cause a violation of the standard, while other commenters recommended a single emissions threshold of 1,000 tpy and provided modeling analyses of different sources as an indication that sources less than 2,000 tpy caused modeled violations. These comments demonstrate that ambient SO<sub>2</sub> impacts can be variable, and are dependent on many factors other than annual emissions (such as meteorology, stack height, local topography and plant operations). These factors can only be assessed through analytical approaches, such as ambient monitoring or air quality modeling, which take many of these related factors into account simultaneously. These comments demonstrate why air quality characterization of the area around these sources is needed to protect public health in the first place.

The EPA believes that, for the purposes of establishing a minimum threshold that prioritizes the resources that will be devoted to characterizing air quality near SO<sub>2</sub> sources nationally, the 2,000 tpy source emissions threshold strikes a reasonable balance between the need to characterize air quality near sources that have a higher likelihood of contributing to a NAAQS violation and the analytical burden on air agencies. This threshold is on the lower end of the range of thresholds recommended by commenters because sources on the lower end of the range have the potential to cause or contribute to violations of the NAAQS. As compared to the preferred option in the proposal (*i.e.*, 1,000 tpy sources in CBSAs over 1 million people; 2,000 tpy sources not in CBSAs over 1 million people), the 2,000 tpy threshold would mean that, in the aggregate, air agencies would need to address air quality near about 35 fewer sources (or 7 percent fewer). Nevertheless, the total emissions addressed would still account for 89 percent of the SO<sub>2</sub> emissions nationally (based on 2011 emissions), very close to the 90 percent level that has been considered to be reasonable by many stakeholders in the past.<sup>4</sup> National SO<sub>2</sub> emissions have declined by a significant amount from 2011 to 2013 (around 1.5 million tons, or more than 20 percent), for various reasons. The EPA assessed the number of sources meeting a 2,000

tpy threshold based on 2013 emissions data now available for EGUs and 2011 emissions data for non-EGUs. Compared to the assessment in the proposal, which assessed the number of sources meeting the proposed threshold (1,000 tpy in urban areas/2,000 tpy elsewhere) based solely on 2011 data, the EPA now estimates that approximately 70 fewer sources (about 15 percent) will need nearby air quality to be characterized than was estimated in the proposal. Based on the updated data, the EPA estimates that already-designated sources plus sources currently exceeding the final threshold in this rule still would account for 86 percent of national emissions. Under this rule, each air agency will be required to identify all sources with annual SO<sub>2</sub> emissions that exceed 2,000 tpy (using emissions data from the most recent calendar year for which such data are available) and characterize air quality around such sources according to the timeline in section IV.C of this preamble.

Of course, if the trend in reduction of SO<sub>2</sub> emissions continues at individual sources, there will also be a corresponding reduction in national emissions, and both kinds of reductions are desirable for improving public health, even if that results in fewer source areas becoming subject to the emissions characterization requirements in the final rule. Conversely, if the trend reverses and source emissions increase, more sources and areas will be required to be characterized under the rule. Thus, the exact number of sources and areas that will exceed the promulgated threshold when air agencies begin characterizing areas under the rule cannot be precisely known at this time, nor can their future percentage share of the national inventory be precisely estimated. Nevertheless, the EPA believes that the promulgated threshold strikes a reasonable balance based on the information the Agency currently has regarding recent historical SO<sub>2</sub> emissions inventory levels. An analysis of potential source threshold options and associated source coverage, emissions coverage, and analytical costs is included in an EPA memorandum to the docket for this rule.<sup>5</sup>

#### d. Discretion To Address Additional Areas

Section 114(a)(1) of the CAA already provides the EPA authority and discretion to require emissions sources

to install, use and maintain monitoring equipment and provide other information as the Agency may reasonably require, even in the absence of this DRR. In addition, the EPA had several reasons for proposing as part of this rule to reinforce state and the EPA discretion to also require air quality characterization around sources with emissions below the proposed thresholds. The purpose of proposing the use of emission levels as the criterion for determining applicability of the air quality characterization requirement is that emissions provide a simple means of identifying the sources that are most likely to cause or contribute to violations of the SO<sub>2</sub> NAAQS. Nevertheless, the EPA recognizes that a variety of factors other than emission levels can influence the likelihood of NAAQS violations. As one example, source characteristics such as stack height and plume buoyancy can significantly affect source impacts. As another example, clusters of multiple smaller sources that are in close proximity can cause as much impact as a single larger source. Finally, the EPA recognizes that a variety of other reasons may exist that may warrant further characterizing air quality in particular areas, which supports maintaining state and EPA Regional Administrator discretion to require air quality characterization in the area. The EPA continues to believe that states and the EPA should retain this authority and that it would be unreasonable to restrict implicitly, via this rule, the inherent authority that air agencies already have to require sources of air pollution to measure their emissions and characterize their impacts.

For these purposes, the EPA continues to believe that the rule should make clear that states and the EPA retain the discretion to subject additional areas to the requirements for air quality characterization beyond areas with a single source exceeding the emissions threshold. The use of a simple emission threshold in the rule provides a convenient means of administering the application of the requirements for air quality characterization for the majority of cases. However, the impacts of a given level of emissions vary substantially, such that many areas with a source or sources that do not exceed the emission threshold might be known to have a high risk of contributing to NAAQS violations, potentially resulting in a higher risk of NAAQS violations than other areas exceeding the emission threshold. As a result, a rule that sets forth minimum requirements based on

<sup>4</sup> The May 2012 White Paper and high-level summaries of stakeholder meetings are available at: <http://www.epa.gov/oaqps001/sulfurdioxide/implement.html>. These documents and written comments received from stakeholders are also included in the docket for this rulemaking.

<sup>5</sup> See also: "Analysis of Source Threshold Options for the Final SO<sub>2</sub> Data Requirements Rule," memorandum to docket EPA-HQ-OAR-2013-0711, July 16, 2015.

an emissions threshold cannot reasonably be used to support an assumption that no further characterization near smaller sources is warranted, or to preclude authority that air agencies already have to investigate the impacts of such sources. Therefore, while this rule requires the air quality characterization near the above-threshold sources, the EPA and air agencies will also need to consult regarding the need for the characterization of air quality near sources below the threshold as well.

Among cases in which no single source meets the applicable emission threshold, no simple indicator is available to indicate which of these cases warrants air quality characterization. For areas with a single source, the areas could warrant air quality characterization if the stack height is low, if the plume rise is minimal, if terrain or meteorology is conducive to high impacts, and/or if emissions are just slightly below the threshold. For areas with multiple sources, concentrations are influenced not only by these stack, terrain and meteorological factors but also by the level of emissions at each source, the distances between them and the wind directions in the nearby area. The EPA appreciates the comments urging the establishment of specific criteria in the rule for identifying additional areas that warrant air quality characterization, but the EPA finds that these areas are better identified on a case-by-case basis reflecting a judgment considering the range of factors that influence the likelihood of NAAQS violations. That is, the EPA agrees with the state commenter urging that the rule provide for discretionary coverage of additional areas, such that additional areas that in the air agency's (and the EPA's) judgment have significant potential for violating the NAAQS can be made subject to requirements for air quality characterization on case-by-case bases.

Consequently, the EPA is retaining the discretion for air agencies and the EPA to require additional areas to be characterized beyond those with a source exceeding the emission threshold. However, the EPA is not revising the rule to establish specific criteria for identifying such areas; the EPA is instead relying on case-by-case evaluation of the various relevant factors to determine which additional areas warrant air quality characterization.

For areas with multiple sources, the EPA recognizes that a number of such areas may have no single source that exceeds the threshold discussed earlier and yet may have concentrations similar

to other areas with a single source exceeding the threshold. Commonly, such areas would have multiple sources clustered in relatively close proximity and would have total emissions at or above the threshold. The EPA envisions the air agencies and the EPA evaluating multiple source areas on a case-by-case basis to determine whether the areas warrant the same priority as areas where a single source has emissions above the threshold. Generally, the EPA strongly recommends that areas with multiple sources, where the combined impact would be expected to be as much as the impact of a typical single source emitting at least 2,000 tpy, should be carefully considered for air quality characterization, and we expect the EPA Regional Administrators to focus on such areas in exercising their discretion. As stated previously, a rule that sets forth minimum requirements based on an emissions threshold cannot also be reasonably used to support an assumption that no further characterization near smaller sources may be required. Therefore, in addition to requiring air quality characterization near sources above the emission threshold, the rule also preserves the discretion of the EPA and air agencies to require air quality characterization in additional areas, which will necessitate consultation on a case-by-case basis regarding the need for characterization of additional areas beyond those containing a source exceeding the threshold in this rule.

Regarding the comments recommending specific criteria for subjecting multiple source areas to the requirements for air quality characterization, the EPA believes that too many factors influence the combined impact for the EPA to establish a single set of criteria for determining whether each area warrants becoming subject to the requirements for air quality characterization. Nevertheless, for the EPA and state agencies considering using their discretion to require characterization of additional areas, the EPA believes that the recommendations of these commenters provide good suggestions for where to begin making such decisions, to be followed by a case-by-case judgment as to the expected degree of combined impacts.

In numerous cases, areas include multiple operations that previously were all part of a single source that now for business reasons have subdivided their ownership, such that the operations that previously were a single source must now be considered multiple sources. For example, in many cases, where previously the area had a

single integrated iron and steel mill, the iron- and steel-making operations now have separate ownership from the coke-making operations, such that the former single source has now become two sources. In these cases, an additional equity concern arises, that otherwise comparable facilities should not be treated differently based on a business decision that has no effect on air quality. If the combined emissions of these now separately-owned operations exceed 2,000 tpy, the impact would commonly be similar to the impacts of single facilities emitting over 2,000 tpy, and such groups of separately owned operations would thus warrant air quality characterization.

Regarding the commenters who recommended that the EPA stipulate that an area with multiple sources emitting less than the threshold should not be required to characterize air quality under the rule unless the combined emissions exceed the threshold, the EPA does not agree with this approach. Even for single source areas, the EPA is preserving the discretion air agencies and the EPA already have to require air quality characterization where the source emits less than the threshold but where concern about potential NAAQS violations warrants further air quality characterization. By the same logic, the combined impacts of multiple sources may warrant further characterization even if the combined emissions are less than the threshold.

### *C. Data Requirements and Program Implementation Timeline*

#### *1. Overall Timeline*

##### *a. Summary of Proposal*

In the proposed rule, the EPA proposed an implementation timeline addressing feedback and concerns raised in previous stakeholder meetings, which the EPA considered to provide air agencies with sufficient flexibility and time to pursue either improved monitoring or modeling to characterize air quality. The EPA designed the schedule to allow air agencies to account for SO<sub>2</sub> reductions that will occur over the next several years as a result of implementation of national and state level programs and facility decisions for complying with such requirements (such as the Mercury and Air Toxics Standards (MATS)).<sup>6</sup> The

<sup>6</sup> In 2012 the EPA promulgated the Mercury and Air Toxics Standards under Section 112 of the CAA, 42 U.S.C. 7412, that set emission limits for several hazardous air pollutants. See 77 FR 9304 (Feb. 16, 2012). Installing the technology necessary to reduce emissions directly regulated by the MATS rule has already reduced the emissions of SO<sub>2</sub>. Id.

EPA solicited comments on the feasibility of the implementation of the proposed timeline. See 79 FR 27456, May 13, 2014. The notice of proposed rulemaking also included a discussion of when the EPA envisioned the information could potentially be used in designation actions.

#### b. Brief Summary of Comments

Several state and industry commenters agreed that the EPA's proposed timeline was reasonable for acquiring data by either modeling or monitoring, and for evaluating the submitted data. Many also agreed that it would be a reasonable schedule for supporting the issuance of designations and submittal of any SIPs, provided future schedules for those actions accommodate the schedule for implementing the rule. However, a larger number of state and industry commenters asserted that the time allotted for installation of monitors was not sufficient. One state commenter stated that the feasibility of the schedule will depend upon the threshold option selected by the EPA. Another state commenter supported the timeline that the EPA proposed as long as the EPA finalizes the rule by late 2014 and added that, if promulgation is delayed, the timeline should be adjusted by as many weeks or months as the delay in finalizing the rule. Some state and industry commenters recommended an extension of at least 1 year on all the proposed actions listed in the implementation timeline. Other commenters felt that the proposed timeline was flawed for multiple reasons and is, therefore, not achievable.

#### c. EPA Response

The EPA recognizes the logistical and financial challenges that were identified by commenters with respect to the timeline. In response, the final rule contains changes to provide additional time for air agencies to determine whether to use modeling or monitoring to characterize air quality near their affected sources, discussed later in this section. However, the final rule retains the proposed deadlines for commencing monitoring or providing modeling. The Agency acknowledges that these deadlines do not provide as much time as some commenters would prefer; however, the EPA believes that these deadlines can be achieved with the appropriate planning, coordination, and program implementation by air

agencies. The EPA notes that if air agencies conclude that the timeline and resource burdens associated with installing and conducting improved monitoring are not feasible for particular areas, they may instead choose the modeling approach, which is generally less expensive and can be performed more expeditiously than monitoring, to characterize air quality. Alternatively, in some cases the source owner and the air agency may be able to establish by January 2017 a federally enforceable requirement limiting emissions to less than 2,000 tpy, with the result that further modeling or monitoring in that area would not be required under the rule unless air agencies or EPA Regional Administrators conclude it is otherwise warranted. Because the purpose of this rule is to obtain improved air quality information in an efficient manner in order that these data may be used in future actions (such as area designations, redesignations, or other actions designed to ensure attainment of the 2010 SO<sub>2</sub> NAAQS) to protect the public from the short-term health effects associated with exposure to SO<sub>2</sub> concentrations that exceed the NAAQS, the EPA believes it would not be appropriate to further extend the timelines for air quality characterization in the rule.

The EPA believes that any further delay in air quality characterization around sources identified as a result of this rulemaking would delay the implementation of the SO<sub>2</sub> NAAQS and, therefore, would impede public health protection in areas that in the future show violations of the standard based on the data to be gathered under the rule. The EPA also believes that any significant delays in monitors becoming operational past the date of January 1, 2017, will certainly delay the potential for monitoring data to be used to inform actions that depend upon ambient concentration assessments, possibly past calendar year 2021. Finally, the EPA notes that under the terms of the March 2015 consent decree, in order to avoid the EPA being required to designate an area by December 31, 2017, an air agency will need to have installed and begun operating the new SO<sub>2</sub> monitoring system no later than January 1, 2017.

The Agency believes that it is very important to maintain the proposed timetable for conducting modeling and installing monitoring sites because of the need for these new data to be

available to support future determinations concerning the attainment status of areas. The EPA encourages each air agency to engage in early dialogue with the appropriate EPA Regional Office and with the identified applicable facilities in order to meet the requirements of the rule. In particular, in light of the reality of the sometimes complex process of identifying potential monitoring locations, securing funding, and installing an appropriate number of new sites, if an air agency is considering the monitoring approach for one or more areas, early coordination should improve the air agency's potential for success in meeting the timing and requirements of the rule.

The final rule retains the January 15, 2016, date for submittal of a list of sources, because the EPA expects that this information is relatively straightforward to obtain, and it is beneficial for planning purposes to have this list available as soon as possible. However, as mentioned previously, in light of comments, the EPA is promulgating a schedule that provides an additional six months for the air agency to specify how it plans to address the area around each listed source. The EPA is promulgating a schedule in which July 1, 2016, is the deadline for selecting among the monitoring approach, the modeling approach, or establishing source emission requirements. If the air agency selects the monitoring approach for a source area, it must also include in the annual monitoring plan (also due by July 1, 2016) information about any new monitoring sites it will establish by January 1, 2017. If the air agency selects the modeling approach for a source area, it must also submit a modeling protocol at that time. If the air agency chooses the option of establishing an enforceable source limit or limits as an alternative to air quality characterization, it must also at that time provide a description of the planned emission limitation, including such information as emission rate, averaging time, and expected legal mechanism for making the limitation federally enforceable. To suffice as an alternative to the characterization requirement, the emission requirements or limits would need to be adopted by the air agency, made federally enforceable, and require compliance by January 13, 2017. Further discussion of the rationale for these revisions to the timetable is provided in the relevant subsections that follow. Table 1 shows

at 9305. On April 15, 2014, the D.C. Circuit denied 26 consolidated petitions for review of the MATS rule brought by state, industry, and environmental petitioners in *White Stallion Energy Ctr. v. EPA*, No.

12–1100 (and consolidated cases) (D.C. Cir.). The Supreme Court has reversed and remanded the D.C. Circuit's decision for further proceedings. *Michigan v. EPA*, Nos. 14–46, 14–47, 14–49, 2015 WL

2473453 (June 29, 2015). However, the MATS rule remains in effect at this time.

the final rule timetable, including this revision.

TABLE 1—TIMELINE FOR DRR IMPLEMENTATION

Date	Action
From promulgation of this rule to January 15, 2016.	Air agency and the EPA Regional Office consult on list of SO <sub>2</sub> sources; air agency submits its list of sources to EPA by January 15, 2016.
July 1, 2016 .....	Air agency specifies for each source whether it will characterize air quality with modeling, characterize air quality with monitoring, or establish a federally enforceable requirement limiting annual emissions of the source to less than 2,000 tpy. For source areas to be modeled, the air agency submits a modeling protocol. For source areas to be monitored, the air agency submits information about any new monitoring sites it will establish by January 1, 2017. For areas where enforceable emission limits will be established as an alternative to air quality characterization, the air agency submits a description of the planned emission limit.
January 1, 2017 .....	Air agency ensures that SO <sub>2</sub> monitors to satisfy the Data Requirements Rule are installed and operational.
January 13, 2017 .....	For any source identified for modeling pursuant to the July 1, 2016, milestone, air agency submits modeling analyses. For any source identified for emission limit approach, air agency submits documentation showing that limits requiring annual emissions to be less than 2,000 tpy are effective and federally enforceable.
May 2020 .....	For any source area identified for monitoring approach, air agency certifies 2019 monitoring data, enabling official design values for the 2017–2019 time period to be calculated.

In addition, while the proposed rule discussed how the timing of the implementation of this rule would fit with the anticipated schedule for completing area designations, the proposed rule did not itself purport to establish a binding schedule for

completing designations. Table 2 provides information concerning the schedule for taking action to designate areas in the future in accordance with the March 2015 consent decree, but is intended for informational purposes only. In this rulemaking, we are not

addressing comments received on the proposed rule concerning the designation process because those issues would be beyond the intended scope of this rulemaking.

TABLE 2—ANTICIPATED SCHEDULE FOR FUTURE ROUNDS OF SO<sub>2</sub> DESIGNATIONS

July 2016 .....	Date by which the EPA must issue final designations for sources meeting specific criteria in the March 2015 consent decree.
August 2017 .....	Expected date by which the EPA would notify states of intended designations based on air quality data obtained pursuant to the first round of the data requirements rule.
December 2017 .....	Date by which the EPA must issue final designations for a majority of the country (pursuant to March 2015 consent decree), except for areas with new monitoring networks commencing operation by January 1, 2017.
August 2019 .....	Anticipated due date for state attainment plans for areas designated nonattainment in 2017.
May 2020 .....	Certification of 2019 monitoring data is required by this date.
August 2020 .....	Expected date by which the EPA would notify states of intended designations for the remainder of the country.
December 2020 .....	Date by which the EPA must issue final designations for the remainder of the country (pursuant to March 2015 consent decree).
August 2022 .....	Anticipated due date for state attainment plans for areas designated nonattainment in 2020.

## 2. Issues Related to Submittal of List of SO<sub>2</sub> Sources Where Air Quality Is To Be Characterized, and Election of Modeling or Monitoring

### a. Submittal of List of Sources Where Air Quality Is To Be Characterized

#### i. Summary of Proposal

In § 51.1203(a), the EPA proposed to require each air agency to submit to its respective EPA Regional Administrator by January 15, 2016, a list identifying the specific sources in the state around which SO<sub>2</sub> air quality is to be characterized. The EPA stated that this proposed requirement for the air agency to submit a list of source areas identified for further air quality characterization,

and the other data submittal requirements found in § 51.1203 of the proposed rule, are appropriate steps necessary to characterize SO<sub>2</sub> air quality throughout the country, and are consistent with sections 110(a)(2)(B), 110(a)(2)(K) and 301(a)(1) of the CAA. In the docket, the EPA provided a preliminary list of sources that appeared to meet the EPA's proposed thresholds (based on 2011 emissions data), and the EPA solicited comments on this list. *See* 79 FR 27446, 27461, May 13, 2014.

#### ii. Brief Summary of Comments

Some state and industry commenters opposed the requirement that, by January 15, 2016, air agencies must

submit a list of sources. Some commenters also stated that submitting a list of sources is unnecessary for various reasons such as data are already made publicly available on an annual basis through the national emissions inventory; that it does not make sense to establish a list that is expected to change; and that air agencies and the EPA can work cooperatively without a binding requirement. Commenters also recommended that any listing of sources, and any identification of the selected air quality characterization approach for specific source areas, should wait until the January 2017 analysis for individual sources or areas is to be completed. One state commenter

indicated that they did not find merit in the citations that the EPA provided in the proposal regarding the authority for requiring this list submittal. This commenter stated that the CAA section 110(a)(2) citations address the requirements for SIP submittals by states for implementation, maintenance and enforcement of the standard. Several state commenters also suggested updates or revisions to the EPA's preliminary list of sources potentially subject to this rule.

### iii. EPA Response

The EPA does not agree with commenters who claim that submittal of an initial list of sources near which air quality is to be characterized is not needed in January 2016. The EPA believes that it is important to receive the list of source areas to be characterized under the rule by January 15, 2016, because it will provide timely clarity for both EPA and the air agency about which sources and associated areas are to be characterized for air quality under this rule. In EPA's judgment, such timely clarity is essential to the success of the characterization efforts that follow the source identification step. The list will identify the sources in the state that exceed the 2,000 tpy emissions threshold based on the most recently available emissions data, as well as any other source or sources identified by the air agency or the EPA Regional Administrator as warranting air quality characterization. Development of this initial list will be important for air agencies as they prepare to generate timely air quality information that may be used to inform future designation, redesignation, or other decisions concerning attainment of the 2010 SO<sub>2</sub> NAAQS.

Retaining this deadline will provide the early opportunity for the air agency and the EPA to discuss and resolve questions about whether air quality characterization should be required for a particular area if, for example, emissions are low in some years and high in others, if an area has a cluster of smaller sources, or if source-specific or other factors may warrant the need for air quality characterization. As a further example, there may also be situations for which the state and the EPA need to reach agreement on what constitutes the most recent year of emissions data for specific EGU and non-EGU sources. The list requirement and deadline will ensure resolution of such questions in time to enable further characterization requirements to be met.

Thus, the EPA is retaining the January 2016 deadline, as proposed, for

submittal of the list of sources in order to initiate an orderly process to obtain additional information on ambient SO<sub>2</sub> concentrations, and ensure these data are available to support actions taken for the implementation of the 2010 SO<sub>2</sub> NAAQS. While the Agency has previously acknowledged that some of the deadlines in this rule do not provide as much time as some commenters would prefer, the EPA believes that the schedule for providing the list of sources is a relatively straightforward exercise that can be accomplished within the required time frame.

The EPA strongly encourages each air agency to consult with its respective EPA Regional Office to identify sources exceeding the emission threshold in the final rule, and to identify any other areas near sources that do not exceed the emission threshold but which would be appropriate for further air quality characterization. It will be important for air agencies and the EPA to carry out this consultation process as early as possible and to reach agreement on the list of sources to characterize under the rule as quickly and efficiently as possible. It is also important to note that, due to the overlap between the criteria for inclusion of sources in this final rule and those in the March 2015 consent decree, all of the sources identified in the March 2015 consent decree should also be included on the January 2016 list of sources required for characterization under this rule. The consent decree requires the designation in July 2016 of areas associated with an initial list of sources meeting specific criteria. Depending on the specifics of those designation actions, information developed to support those actions may serve to meet some or all of the requirements of this data requirements rule. (See section IV.E, Other Key Issues and Comments, for more discussion of these issues.)

Regarding comments about EPA's authority to require submittal of a source list, the EPA believes that the requirements of this rule for air agencies to submit a list of source areas identified for further air quality characterization, and the other data submittal requirements found in § 51.1203 of this rule are appropriate steps needed to better understand SO<sub>2</sub> air quality throughout the country, and that including such requirements is consistent with sections 110(a)(2)(B), 110(a)(2)(K), and 301(a)(1) of the CAA.

Section 110(a)(2)(B) of the CAA indicates that state SIPs are to "provide for establishment and operation of appropriate devices, methods, systems, and procedures necessary to (i) monitor, compile and analyze data on ambient air

quality and (ii) upon request, make such data available to the Administrator." Section 110(a)(2)(K) of the CAA states that SIPs shall "provide for (i) the performance of such air quality modeling as the Administrator may prescribe for the purpose of predicting the effect on ambient air quality of any emissions of any air pollutant for which the Administrator has established a NAAQS and (ii) the submission, upon request, of data related to such air quality modeling to the Administrator." Although both of these provisions direct what air agencies are required to include in SIPs, they clearly support the authority of the EPA to prescribe requirements that the information that SIPs are to ensure can be provided is collected in the first instance.

In addition, CAA section 301(a)(1) provides the EPA with general authority to establish regulations as necessary to carry out the agency's functions, which in this case includes ensuring that additional information is collected and provided so that air agencies and the EPA can ensure attainment and maintenance of the SO<sub>2</sub> NAAQS throughout each state. Finally, the EPA notes that CAA section 114(a)(1) also provides broad authority for the EPA, for the purposes of developing any implementation plan under section 110 or carrying out any provision of the CAA, to require monitoring and provision of other information the Agency may reasonably require (such as modeling information).

The EPA appreciates the comments on the preliminary list of sources that appeared likely to be subject to this rule as proposed. The EPA acknowledges that, for various reasons, such a list of sources could change up until the time that the list is required to be submitted. Accordingly, such a list is not being promulgated as part of this rule. The EPA plans on continuing consultations with air agencies regarding the source areas that the final rule will require to be characterized.

## b. Choice Monitoring or Modeling

### i. Summary of Proposal

In § 51.1203(b), the EPA proposed to require each air agency to state whether it will characterize air quality through improved ambient air quality monitoring or through air quality modeling techniques by January 15, 2016. The EPA also proposed in § 51.1203(b) that in an area with multiple subject sources, the air agency (or air agencies if a multi-state area) shall use the same technique (monitoring or modeling) to characterize air quality for all sources in the area. For

situations where multiple sources are located in proximity across state boundaries, the EPA recommended that the relevant air agencies work together to determine a common analytical approach for assessing air quality in that area. *See* 79 FR 27460, May 13, 2014.

#### ii. Brief Summary of Comments

Several state and industry commenters stated that the EPA should provide a more reasonable schedule for air agencies to elect the monitoring option under the proposed rule. Some commenters suggested that air agencies should have until January 1, 2017, to make this determination because they could benefit from using initial modeling results to inform this decision, such flexibility would reduce burdens on state regulators, and it could lead to more accurate determinations, while not impacting the EPA's expected attainment dates for such areas should the areas become designated nonattainment.

#### iii. EPA Response

In response to these comments, the EPA is providing additional time for making the election of modeling or monitoring (or, as discussed later, for making the election of an alternative approach that enforceably limits an applicable source's emissions). Accordingly, the deadline for this election will be July 1, 2016. The EPA recognizes that evaluating the relative merits of modeling and monitoring for any particular area, including identification of funding sources for any new monitoring that might be under consideration, warrants more time than was provided under the proposed rule. Consistent with this revision, the EPA is also revising the deadline for air agencies using modeling to submit modeling protocols for the applicable areas. Thus, under the final rule, by July 1, 2016, the air agency must submit its selection of whether each area will be characterized through modeling or monitoring and, depending on that selection, either must submit a modeling protocol or must include information in the Annual Monitoring Network Plan that specifies the monitoring to be conducted to address the requirements of this rule. The EPA believes that this revised deadline still provides for timely planning for air quality characterization to occur (through modeling) or begin (through monitoring) at the beginning of 2017. Conversely, the EPA does not agree that any later deadline for selecting the means of addressing air quality characterization requirements would provide the time and flexibility to

address in a timely way any issues that arise after the selection is made. The result would be that a later deadline for this selection could jeopardize timely receipt of information characterizing air quality.

Notwithstanding this revision, the Agency encourages air agencies to start their investigation of this issue as soon as practicable. The EPA strongly encourages each air agency to consult with its respective EPA Regional Office to identify sources exceeding the emission threshold in the final rule and any other sources that do not exceed the emission threshold but near which further air quality characterization would be warranted. Similarly, the EPA strongly encourages air agencies to hold early discussions regarding the manner in which modeling or monitoring might be used. As one example, if the air agency believes that the existing monitoring network suffices to characterize air quality, early discussions with the EPA would be essential for assuring that the intended selection of monitoring is based on appropriate assumptions regarding the network's ability to characterize air quality near the applicable source(s) without further network adjustments.

#### c. Use of Most Recent Publicly Available Data

##### i. Summary of Proposal

In § 51.1202, the EPA proposed that the air agency should identify applicable sources of SO<sub>2</sub> based on the most recent publicly available annual SO<sub>2</sub> emissions data for such sources. The EPA specified in proposed § 51.1200, that "annual SO<sub>2</sub> emissions data" means the quality-assured annual SO<sub>2</sub> emissions data for a stationary source as reported to the EPA in accordance with any existing regulatory requirement (such as requirements to report continuous emissions monitoring data for EGUs subject to the acid rain program). The EPA stated that, by January 15, 2016, data for 2014 would be available for EGU sources and 2013 data would be available for non-EGU sources. By considering the most recent emissions data, the EPA noted that air agencies and the EPA will be able to take into account any recent emissions increases or decreases that would cause a source to be subject to the requirements in this proposed rule. The EPA included in the docket to the proposed rule a preliminary list of sources that appeared to meet the criteria described in the EPA's proposed source threshold approach and requested that air agencies provide in their comments on this proposed rule

any relevant updated information that would support the addition or removal of a source from that preliminary list. *See*, 79 FR 27457, May 13, 2014.

#### ii. Brief Summary of Comments

Several state and industry commenters generally supported the approach that the basis for the emissions to be compared to the threshold would be the latest available 1-year of SO<sub>2</sub> emissions data. One industry commenter stated that using the most recent year of data ensures that any recent emissions reductions that have occurred will be properly taken into consideration.

One public interest group commenter stated that using the most recent year as a snapshot may fail to capture sources that simply have a low year, but normally emit at higher levels, and recommended that the EPA require that facilities only be excluded under the threshold if, in prior years, the facilities had similar low total emissions below the limit. A number of states provided information suggesting specific modifications to the EPA's preliminary list of sources.

One commenter stated that the rule should not take an "all in" or "all out" approach based on a simple analysis of 1 year's emissions or even a 3-year average of emissions alone. The commenter stated that the EPA seems to allow, or consider, the potential addition of non-threshold-meeting sources but does not appear to recognize that there may be instances where the air agencies knowledge and judgment warrants exclusion of threshold triggering sources. They suggested that air agencies should be able to take into consideration operational changes during the 3-year period to determine if a different methodology is appropriate for determining if a source should be a part of the analysis.

#### iii. EPA Response

The EPA continues to believe that the most appropriate generally applicable basis for determining applicability of the air quality characterization requirements is the most recent available year of emissions data for a stationary source as reported to the EPA in accordance with any existing regulatory requirement. As we have previously explained, SO<sub>2</sub> emissions are trending downward, due to numerous national and regional requirements that have recently been adopted and are taking effect. The Agency believes it is reasonable to account for this trend by basing applicability for this data requirements rule on the most recent available year of emissions.

By January 15, 2016, the EPA would expect that 2014 data will be available for all EGU sources, and 2015 data may be available for many EGUs in accordance with the requirements of the Acid Rain program and other emission trading programs that require data certification soon after the end of the year. These sources report hourly emissions data to the EPA on a quarterly basis. Emissions data for large SO<sub>2</sub> sources also would be available from annual reporting required for the AERR. Every 3 years (*i.e.*, 2011, 2014, 2017 and so on), air agencies must submit to EPA emissions data for SO<sub>2</sub> sources with the potential to emit more than 100 tpy. In other years, the AERR requires states to report emissions data for SO<sub>2</sub> sources with the potential to emit more than 2,500 tpy. These annual reports under the AERR are due 12 months after the end of the emissions year. Thus, the EPA would expect that in January 2016, states would have emissions data for calendar year 2014 available for non-EGU sources over 100 tpy potential to emit. Emissions reporting requirements for the Acid Rain and AERR programs would be expected to cover the vast majority, if not all, of the sources subject to the SO<sub>2</sub> DRR.

By considering the most recent emissions data, the air agency and the EPA will be able to take into account any recent emissions increases or decreases that would cause a source to be subject to the requirements in this rule or not. Although identifying sources based on the most recent year of emissions is a reasonable basis for prioritizing limited modeling and monitoring resources for characterizing current air quality, the EPA recognizes the concern of some commenters that there may be sources that in the most recent year have emissions that are lower than normal and are not representative of normal operations. In these cases, *i.e.*, where recent emissions are below 2,000 tpy but no controls have been installed and past representative emission levels are typically above 2,000 tpy, the state and the EPA should consider using their discretion to require additional air quality characterization near such sources.

The EPA also recognizes the concern about sources for which the most recent year's emissions are unrepresentatively high, *i.e.*, that some sources may have recent year emissions above 2,000 tpy but normally emit below that level. Given the trends in emissions, the EPA believes that situation will be relatively rare. Moreover, the existence of such sources does not negate the general conclusion that recent emissions data are an appropriate means for targeting

limited modeling and monitoring resources for characterizing current air quality.

The EPA believes that a rule that prioritizes resources based on the most recent year's data is more appropriate for a broader range of circumstances. The EPA notes, however, that after a source is initially identified, the air quality characterization requirements require air agencies to provide at least 3 years of monitoring or modeling data. The availability of such data will provide the opportunity to give appropriate consideration to representative emissions when using such data, as appropriate to the specific use.

#### d. Shutdowns and Limitations on Emissions Levels by January 13, 2017

##### i. Summary of Proposal

The EPA noted in the proposed rule that there may be sources in the power industry and other sectors that are in operation as of January 15, 2016, but may be scheduled to shut down (*e.g.*, due to a consent decree or other legal requirement), or may choose to shut down, prior to January 2017 (when the air agency should have ambient monitors operational and air quality modeling completed). The EPA proposed that any applicable source that intends to shut down but is still in operation on January 15, 2016, should be included on the air agency's list for SO<sub>2</sub> air quality characterization. However, if by January 13, 2017, the air agency can provide the EPA with a legal agreement confirming that the listed source has permanently and enforceably shut down, then under the proposal the air agency would have no further obligation regarding air quality characterization for this source pursuant to this rulemaking. *See* 79 FR 27458, May 13, 2014.

##### ii. Brief Summary of Comments

One state commenter recommended that the EPA revise the rule to exempt from the list those sources that take an enforceable emission limitation below the 2,000 tpy emissions threshold before January 13, 2017, even if reductions and applicability of the limitation are only realized within a reasonable time after January 13, 2017. Several commenters stated that there is no basis to distinguish between situations in which a source may provide documentation it will shut down, and cases where an enforceable limit is established, because in each case the source would no longer meet the criteria for characterization under the rule. Another commenter stated that sources should be able to

take federally enforceable limits on a tpy basis prior to the January 13, 2017, date for air agencies to submit their modeling analysis to avoid characterization under the rule. Another state commenter stated that requiring sources to implement controls prior to submittal of future required SIPs would encourage sources to make emission reductions while allowing sufficient time to implement these actions.

Some state and industry commenters recommended that sources should have until the applicable attainment date for a designated nonattainment area to complete any enforceable actions that achieve attainment, provided those actions are committed to by January 13, 2017. Commenters stated that there is insufficient time for sources to take all the actions needed to implement these controls (including conducting modeling, determining the required reductions and control strategies, procuring capital funds, obtaining permits and installing equipment) under the proposed rule. Commenters stated that allowing sources to implement controls after January 13, 2017, but before future attainment dates supports the EPA's desired outcome of achieving emission reductions as quickly as possible; in contrast, under the EPA's proposal, sources unable to have enforceable limits in place by the January 13, 2017, deadline have little incentive to take any action prior to the anticipated designation deadline of 2020.

##### iii. EPA Response

The EPA is finalizing the proposed approach to allow a state with a source that is in operation as of January 15, 2016, but that provides documentation that the source will shut down permanently prior to January 13, 2017 pursuant to a federally enforceable mechanism (*e.g.*, source-specific SIP revision or minor NSR permit revision submitted to the EPA by January 13, 2017), to avoid being subject to the requirement to characterize air quality in the vicinity of the source.

As a result of comments received on the proposed rule, the EPA is clarifying how this exclusion would work relative to the requirement for development and submittal in January 2016 of the list of sources near which air quality is to be characterized. The EPA appreciates that there might be a source whose most recent year of actual emissions exceeds the threshold for inclusion on the list, but for which the state has already adopted, or will soon adopt, enforceable requirements to shut down by January 2017. Such a source may have significant emissions during the most

recent available year, or may even still be in operation on January 15, 2016. The EPA has determined that the clearest way to implement the exclusion from the air quality characterization requirement is to require that the air agency initially identify such a source on its list for SO<sub>2</sub> air quality characterization because emissions in the previous year, which serve as the basis for listing under this rule, exceeded the emissions threshold. However, the final rule now includes language in § 51.1203(b) allowing the air agency to indicate by July 1, 2016, that it will provide the EPA with a federally enforceable requirement confirming that the source will be permanently and enforceably shut down by January 13, 2017. For a source for which the air agency provides documentation of a federally enforceable requirement that the source will shut down, the air agency will have no further obligation regarding air quality characterization pursuant to this rulemaking. This approach accomplishes the intent of the proposal by implementing the approach in a more clear and straightforward manner.

Commenters on the proposed rule also suggested that, in a similar manner, an air agency should not be subject to the air quality characterization obligation for any source that is initially on the list of sources due in January 15, 2016 (based on most recent actual emissions), but that becomes subject to a federally enforceable requirement to limit annual SO<sub>2</sub> emissions to below the 2,000 tpy emissions threshold. The EPA finds merit in those comments that suggest that the rule allow for similar treatment for sources that become subject to a federally enforceable emission limit as is allowed for sources that provide documentation that they will shut down. The EPA has revised the final rule accordingly, and provides further discussion below. However, EPA does not agree with commenters who suggest that sources should have until the applicable designation date, or attainment date for an area that is designated nonattainment, to implement controls that were committed to prior to January 13, 2017. Relying on commitments for emission reductions to occur after 2017 would not be consistent with the main focus of this rule, which is to provide current, updated information on priority SO<sub>2</sub> sources to the EPA beginning in early 2017 that will inform future area designations (now required in December 2017 and December 2020 per the March 2015 consent decree).

As indicated above, a source would be listed for air quality characterization if

its most recent emissions were above the 2,000 tpy threshold. However, the final rule also allows the air agency to meet the requirements of this rule by submitting a federally enforceable emissions limitation (e.g., source-specific SIP revision or minor NSR permit revision) to the EPA by January 13, 2017, that requires the affected source to reduce allowable emissions at the source to an annual rate below the 2,000 tpy threshold level by January 13, 2017. By July 1, 2016, the air agency would be required to identify the sources on the list for which it would be using such an approach as an alternative to modeling or monitoring. For such a source identified on the list, if the affected air agency has adopted and the source has become subject to federally enforceable control measures lowering emissions below 2,000 tpy by January 13, 2017, the air agency will generally not be required to further characterize the impacts from the source's emissions solely due to its size as of January 15, 2016.

Although air agencies may follow this option as an alternative to characterizing areas with sources that limit their emissions to below the 2,000 tpy size threshold, the EPA believes that air agencies and the EPA must apply judgment as to whether there are still reasons to characterize these areas due to other factors. As discussed above, some areas where all sources emit less than 2,000 tpy may nevertheless warrant air quality characterization, for example because the area has a cluster of sources with intermediate emission levels or because the characteristics of a source or the area warrant it. Thus, some areas with all sources limited to below 2,000 tpy may still warrant air quality characterization. Therefore, the EPA urges air agencies to consult early with the EPA regarding areas that are under consideration for being addressed in this manner, in order to develop a common understanding as to whether emission limits under consideration would suffice as an alternative to air quality characterization for the area.

The EPA believes that allowance for this alternative emission limit approach is not only consistent with the intent of this rule to prioritize resources to focus on the largest sources of SO<sub>2</sub>, but it also has the additional benefit of providing an incentive for early emission reductions to occur which will improve air quality in these areas in an expeditious manner. However, we do acknowledge the distinction between a formerly large source with no future emissions and a source with reduced but continuing emissions. The Agency does not believe it would be appropriate

to provide that the latter source can be excluded from evaluation in all cases. It may be that a source with emissions newly limited to below the applicability threshold—particularly one with limits established just below the threshold—may warrant further characterization, just as a source with actual emissions below the threshold may warrant characterization in some instances. For example, air quality characterization would continue to be warranted in areas with other sources over the applicability threshold, and in areas where no single source has emissions over the threshold but the combined emissions of multiple sources warrant air quality characterization. In evaluating such cases, the air agency should account for all source emissions contributing to ambient concentrations in the area, including those remaining emissions from the source that has just reduced its levels to below the applicability threshold. For this reason, the rule does not automatically exempt sources with emissions limited to less than 2,000 tpy from air quality characterization requirements; the rule instead provides that the air agency or the EPA may judge that the area should continue to be required to characterize air quality notwithstanding the new emission limits. Air agencies are thus advised to consult with their EPA Regional Office before pursuing this alternative to air quality characterization for a particular source area.

### 3. Issues Related to Submittal of Modeling Protocols

#### a. Summary of Proposal

For source areas that an air agency identifies are to be evaluated through air quality modeling, the EPA proposed in § 51.1203(d) that an air agency must also provide a modeling protocol to the EPA Regional Administrator for review by January 15, 2016. In the proposal, the EPA stated that the EPA Regional Offices would review the submitted information and consult with the air agency as expeditiously as practicable, either approving the submitted information in a similar manner to approval of annual monitoring plan updates, or having further discussion with the air agency if adjustments to modeling protocols are warranted. See 79 FR 27458, May 13, 2014.

#### b. Brief Summary of Comments

Several commenters stated that 1 year is not enough time to complete modeling demonstrations. These commenters stated that depending on the scope of the modeling required, it would take 2 to 4 years to complete the

entire process. The modeling time estimate will increase if refined modeling is required to site monitors and if the EPA expects the states to submit modeling protocols and not conduct any refined modeling to support monitor placement decisions until the EPA approves the protocols.

Several state and industry commenters objected to the EPA oversight of the modeling protocols. Commenters were concerned that the EPA could not review the plans in a timely manner and could cause delays in the process. One state commenter stated that, if this oversight and approval is finalized in this rule, they have serious concerns about whether 2 years from promulgation of the final rule is a reasonable amount of time for air agencies to prepare the necessary data inputs and conduct such modeling for all subject sources. One state commenter suggested that the EPA should clarify that air agencies could provide to the EPA a modeling protocol framework for review and approval, and that source-specific review of protocols should be left up to the respective state agency, consistent with past practices in PSD SIP approved states as well as past practices supporting Best Available Retrofit Technology (BART).

Some state and industry commenters recommended that the EPA oversight/approval of model protocols should be eliminated and air agencies should be able to determine the best approach, using the normal course of discussion and cooperation with their respective EPA Regional modeling contacts, and document that approach with the final submittal to the EPA. One industry commenter stated that it is arbitrary and capricious to require EPA approval of state monitoring and modeling plans when the EPA's technical resources are too stretched to provide this oversight in a timely manner.

#### c. EPA Response

The EPA recognizes the concerns of the commenters about the time and resources needed to develop effective modeling protocols. To clarify, the final rule does not require EPA approval of modeling protocols before air agencies may begin conducting modeling, but does direct air agencies to submit to the EPA modeling protocols by July 1, 2016. As with the modeling itself, directing submission of protocols is within the EPA's authority to prescribe modeling for the purpose of predicting the effect on ambient air quality of emissions under CAA section 110(a)(2)(K), and to prescribe such regulations as are necessary for the EPA to carry out its functions under CAA section 301(a)(1).

It is reasonable for the EPA to establish a process that provides an opportunity for preliminary EPA assistance to air agencies to ensure that their subsequent modeling is conducted in a manner that results in information that can reliably inform subsequent EPA actions determining air quality status under the SO<sub>2</sub> NAAQS. As explained below, the submission of modeling protocols will increase the likelihood that subsequent air agency modeling is sufficient for this purpose, and thus will clearly assist the EPA in carrying out its functions of determining air quality status.

As noted above, the EPA is allowing air agencies approximately six additional months to determine whether to characterize air quality through modeling or monitoring in order to accommodate the concerns about time needed to make this determination, without delaying the date by which information for characterizing air quality becomes available. Consistent with this revision, the EPA is delaying the deadline for states to submit modeling protocols for sources for which they choose to characterize air quality through modeling, to match the July 1, 2016, deadline for selecting an air quality characterization approach. The EPA believes that it is important and valuable for the EPA Regional Offices to work closely with air agencies to ensure that modeling protocols are adequate to ensure that the modeling for sources accurately characterizes air quality near sources. Requiring modeling protocols will help to keep air agencies from getting too far into the modeling process in a manner that may not be appropriate, which could occur absent such preliminary consultation with the EPA and, if it occurred, could result in the air agency needing to re-conduct modeling after submission to the EPA. The EPA does not intend to formally approve these protocols, nor does the EPA believe that a one-size-fits-all timeline, process, or presumption regarding approval or disapproval of these protocols is warranted. Nevertheless, the EPA believes that submittal of protocols will facilitate identification, and resolution of modeling issues, and will thereby help to avoid a later situation in which the EPA would not be able to rely upon the air agency's modeling in subsequent actions determining air quality status. Review of modeling protocols by the EPA will help ensure that the air agency's modeling will be appropriate for use in making future determinations regarding areas' attainment status, such as designations or redesignations. If an air agency's modeling protocol is not

submitted in advance of the subsequent modeling, the chances are greater that the EPA may not have critical air quality information when it is needed (for example, when the EPA intends to make area designations). Therefore, the EPA believes that a requirement for the air agency to provide modeling protocols for relevant sources to the EPA Regional Administrator by July 1, 2016 is a reasonable requirement. The modeling protocol should include information about issues such as emissions input data, modeling domain, receptor grid, meteorological data and how to account for background concentrations.

As was the case for the development of the list of sources and characterization approaches, the Agency acknowledges that the schedule for state submittal and the EPA review of modeling protocols is expeditious. The EPA nevertheless believes that the schedule can be achieved with appropriate planning, coordination, and program implementation by air agencies, and believes that it is necessary to establish expeditious timelines to ensure timely availability of the air quality information. The EPA Regional Office staff will be available to consult with air agency officials to refine the modeling protocols for relevant sources. The EPA Regional Offices will review the submitted information and consult with the air agency expeditiously to discuss any recommended adjustments to the protocol.

#### 4. Issues Related To Submittal of Annual Monitoring Network Plans That Include SO<sub>2</sub> Monitoring Network Modifications To Satisfy the DRR

##### a. Summary of Proposal

In areas where air quality will be characterized through ambient monitoring to satisfy this rulemaking, the EPA proposed monitoring requirements in § 51.1203(c), including the requirement that air agencies submit relevant information about these monitoring sites to the EPA Regional Administrator by July 1, 2016, as part of their annual monitoring network plan, in accordance with the EPA's monitoring requirements specified in 40 CFR part 58. In the proposal, the EPA encouraged air agencies to work with the EPA Regional Offices in the development of an appropriate network plan which would include the rationale for why the proposed number of sites and their individual locations are appropriate. The EPA stated in the proposal that optional considerations for siting these monitors are discussed

in the draft Monitoring TAD.<sup>7</sup> See 79 FR 27458, May 13, 2014.

#### b. Brief Summary of Comments

Several state and industry commenters asserted that it is unreasonable for the EPA to assume monitoring plans can be submitted by the proposed July 1, 2016, deadline. Some commenters stated that it may not be determined that monitoring would be appropriate in certain areas until after a lengthy round of initial modeling is complete. Other commenters stated that siting monitors is a lengthy process which involves, among other steps, working with the sources and the EPA to determine where monitors should be located, obtaining access to sites, identifying funding, and procuring and installing equipment. Furthermore, one commenter stated that, for sources that choose to operate monitoring equipment, additional time will be needed to (1) develop documentation between air agencies and sources to ensure that sites are adequately maintained and that data are reported in a timely and complete manner, and (2) to put in place a quality assurance program consistent with the EPA requirements for the entire monitoring network.

#### c. EPA Response

The EPA is finalizing the requirement that any plans to conduct monitoring to satisfy requirements of this rule (by air agencies, industry, or other parties) shall be reflected in the state's Annual Monitoring Network Plan due by July 1, 2016. The Agency believes that monitoring resources can be appropriately put in place by the January 1, 2017, deadline to satisfy this rule, particularly if air agencies begin planning as soon as possible. The EPA has encouraged air agencies to begin the monitor planning process early, particularly for the largest sources. As stated previously, the EPA believes that while the schedule for meeting the requirements of this rule is expeditious, the schedule can be achieved with the appropriate planning, coordination, and program implementation by affected air agencies. The EPA strongly encourages air agencies to start their investigation of this issue as soon as practicable. The EPA also encourages each air agency to consult with its respective EPA Regional Office to identify sources exceeding the emission threshold in the final rule and any other sources that do not exceed the

emission threshold but which would warrant the characterization of nearby air quality. In addition, as stated previously, the EPA believes that it is necessary to establish expeditious timelines to ensure timely availability of air quality information. With this in mind, and in light of the many logistical concerns raised by commenters and recognized by the EPA, the Agency is encouraging air agencies to engage with their respective EPA Regional Offices well in advance of the time by which the Annual Monitoring Network Plan is due. To this end, states should share their draft SO<sub>2</sub> network design plan for SO<sub>2</sub> monitoring intended to satisfy this rule with the EPA and the public in advance of the complete Annual Monitoring Network Plan.

The reality of the sometimes complex process of identifying a location, securing funding and installing a new monitoring site, necessitates such an approach. The Agency believes that early interaction between air agencies and the EPA Regional Offices and industry will likely improve the potential for success in installing an appropriate number of monitors in appropriate locations around SO<sub>2</sub> emitting facilities identified for characterization in this rulemaking.

#### 5. Issues Related to Deadline for Operation of SO<sub>2</sub> Monitors

##### a. Summary of Proposal

The EPA proposed in § 51.1203(c)(1) that air agencies that have chosen to characterize air quality through ambient monitoring must have any relocated and/or new monitors operational by January 1, 2017. In the preamble, the EPA explained that, under this approach, it is anticipated that the first 3 calendar years of data would be collected from 2017 through 2019, allowing the first design value for each monitor to be calculated by May 2020. This would allow these new monitoring data to be used to inform air agency and the EPA determinations of areas' attainment status in actions that occur in 2020, which could include designations and redesignations. See 79 FR 27458, May 13, 2014.

##### b. Brief Summary of Comments

One industry commenter stated that the proposed rule reflected a reasonable timeframe for air agencies to collect the data, either through monitoring or modeling, that are needed to characterize air quality in areas and determine whether the 1-hour SO<sub>2</sub> NAAQS is being met. One state commenter also asserted that the feasibility of this time period will be

dependent upon the threshold option selected by the EPA and, thus, the number of affected sources.

However, more than 10 state and industry commenters asserted that the short time period between the dates when the monitoring plans need to be submitted and the monitors are required to be operational is inadequate. One industry commenter stated that it is technically infeasible to implement the proposed rule by 2017 and, thus, the EPA's proposal is arbitrary and capricious.

Several state and industry commenters recommended an extension of at least 1 year for air agencies to begin actual monitoring. One state commenter suggested that the EPA should allow monitoring to begin operation between May 1, 2017, and July 1, 2017, which would be consistent with its suggested approach allowing air agencies to notify the EPA of selection of the monitoring option up to January 1, 2017. This commenter recognized that this approach would likely require delaying the attainment date, if designations are not made until after 3 calendar years of the new monitoring data are obtained and certified. This commenter also noted that, if the EPA's approval of an SO<sub>2</sub> monitoring plan under this proposal does not occur until late 2016, air agencies with winter weather concerns would simply not have sufficient time to set up a monitoring network by January 1, 2017. Another state commenter noted that other recent rules establishing new monitoring requirements (such as NAAQS revisions for NO<sub>2</sub>, SO<sub>2</sub> and PM<sub>2.5</sub>) have not required such rapid deployment of monitors, but have each allowed at least 1.5 years from submittal of the network plan to operation of the monitor.

##### c. EPA Response

The EPA recognizes that the logistical and financial burdens of installing an ambient air monitoring station can vary in difficulty and the resources required. However, as noted earlier with regard to the overarching timetables effected by this rule, the Agency believes that, as with other parts of the implementation schedule, while the schedule for operating monitors is expeditious, it can be achieved with appropriate planning, coordination, and program implementation by the air agency which will allow monitoring resources to be in place by the deadline. The EPA believes that any further delay in air quality characterization around sources identified as a result of this rulemaking will delay implementation of the standard and public health protection in areas where there may be a violation of

<sup>7</sup> The SO<sub>2</sub> NAAQS Designations Source-Oriented Monitoring Technical Assistance Document can be found at <http://www.epa.gov/airquality/sulfurdioxide/pdfs/SO2MonitoringTAD.pdf>.

the standard. The Agency believes that it is most prudent to maintain the proposed timetable for monitoring network installation because of the need for use of these new data in a relatively timely manner for use in making attainment status decisions concerning SO<sub>2</sub> areas in the country. Therefore, the EPA is finalizing the date by which monitors being used to satisfy this rulemaking must be operational to be January 1, 2017.

As noted previously, if a state chooses to monitor to satisfy the requirements of this rule, planning for the installation of new monitors must occur early on, soon after this rule is promulgated. With this in mind, and in light of the many logistical concerns raised by commenters and recognized by the EPA, the Agency is encouraging air agencies to engage with their respective EPA Regions well in advance of the time by which the Annual Monitoring Network Plan and network operations are due. The EPA is encouraging air agencies to engage with their respective EPA Regional Offices, and possibly the industrial sources needing nearby air quality characterization, to plan an adequate network design as early as possible after this rule is promulgated. The reality of the sometimes complex process of identifying a location, securing funding and installing a new monitoring site, necessitates such an approach. The Agency believes that early interaction between air agencies and the EPA Regional Office and industry will likely improve the potential for success in installing an appropriate number of monitors in appropriate locations around SO<sub>2</sub> emitting facilities identified in this rulemaking as needing nearby air quality to be characterized. The EPA also notes that if air agencies conclude that the timeline and resource burdens associated with installing and conducting improved monitors are not feasible for particular areas, they may instead choose the less resource-demanding and more expeditious method of modeling to characterize SO<sub>2</sub> emissions impacts in such areas.

## 6. Issues Related To Submittal of Modeling Analyses to the EPA

### a. Summary of Proposal

The EPA proposed in § 51.1203(d)(3) that air agencies that choose modeling to characterize ambient air quality be required to submit modeling analyses to the EPA Regional Office by January 13, 2017. In the proposal, the EPA recommended that these modeling analyses should be conducted in accordance with the recommendations

in the EPA's Modeling TAD<sup>8</sup> or as otherwise agreed upon with the EPA Regional Office on a case-by-case basis. The EPA stated that the EPA Regional Office and the air agency should engage actively in consultation to understand the inputs, assumptions and findings associated with each air quality modeling analysis; the air agency should submit thorough documentation of its modeling analysis; and the air agency should provide the EPA with supplemental information about the analysis upon request.

The proposal also indicated that where areas have not already been designated under the 2010 SO<sub>2</sub> NAAQS, air agencies could submit updated designation recommendations, if appropriate, as informed by their modeling analyses. The proposal noted that in developing any updated designation recommendations, the air agency should follow the EPA's most recent SO<sub>2</sub> designation guidance.<sup>9</sup> See 79 FR 27458, May 13, 2014.

### b. Brief Summary of Comments

One state commenter disagreed with the requirement that comprehensive modeling analyses and related supporting information need to be submitted to the EPA. This commenter asserted that the modeling analyses will be conducted by the facility owners and reviewed by the state air agency, and the air agency should be able to forward just a summary of the analyses to the EPA with sufficient information for the EPA to evaluate.

### c. EPA Response

The EPA is finalizing its proposed approach of requiring that air agencies choosing modeling to characterize ambient air quality be required to submit modeling analyses to the EPA Regional Office. Irrespective of whether the state or a third party conducts the modeling, it is the state's responsibility under the CAA to submit the information that this rule requires. The EPA anticipates that any state submittal of third-party modeling would reflect a review as to whether it believes that the modeling satisfies applicable

<sup>8</sup> The Draft SO<sub>2</sub> NAAQS Designations Modeling Technical Assistance Document can be found at <http://www.epa.gov/airquality/sulfurdioxide/pdfs/SO2ModelingTAD.pdf>.

<sup>9</sup> The EPA issued initial guidance on the SO<sub>2</sub> area designations process on March 24, 2011. See <http://www.epa.gov/air/sulfurdioxide/pdfs/20110411SO2designationsguidance.pdf>. Note: The EPA issued updated SO<sub>2</sub> designations guidance. See "Updated Guidance for Area Designations for the 2010 Primary Sulfur Dioxide National Ambient Air Quality Standard", March 20, 2015. Available at: <http://www.epa.gov/airquality/sulfurdioxide/pdfs/20150320SO2designations.pdf>.

requirements. Moreover, the EPA anticipates that the submittal would provide adequate information for the EPA to review the adequacy of the analysis as well.

### D. Technical Issues Relating to Modeling and Monitoring

#### 1. Technical Assistance Documents (TADs)

This section of the preamble presents a discussion of the threshold-based air quality characterization approach to implement the SO<sub>2</sub> NAAQS in areas that contain sources with larger SO<sub>2</sub> emissions, in order to address areas where there may be higher potential for NAAQS violations that adversely affect public health. This section discusses the different recommended approaches air agencies may use to provide the necessary air quality information to the EPA for areas around those identified sources.

#### a. Summary of Proposal

In the preamble of the proposed rulemaking, the EPA noted that the Agency has produced draft, non-binding Monitoring and Modeling TADs that discuss options, suggested approaches and methods on how monitoring or modeling efforts to characterize air quality around an identified source might be conducted. The EPA stated that these documents can be used to assist air agencies in the implementation of this rulemaking. See 79 FR 27460, May 13, 2014.

#### b. Brief Summary of Comments

One industry commenter stated that the proposed rule references and relies upon guidance provided in the Modeling and Monitoring TADs and in EPA's Guideline on Air Quality Models; therefore, the commenter asserted that the documents are subject to review and comment for the proposed rule. One state commenter asserted that it is challenging to prepare meaningful comments on the proposal since much of it is contingent upon the use of the TADs.

Some state and industry commenters urged the EPA to be clearer in the final preamble that the TADs are guidance and, therefore, are not binding. One state commenter urged the EPA to explicitly state in the final rule that air agencies retain the ability to use alternative methods to those outlined in the TADs. One industry commenter stated that the EPA's reliance on technical guidance documents that have not been subject to public notice and comment undermines protections guaranteed by the Administrative

Procedure Act. One state commenter stated that because the rule “requires” the use of “. . . separate non-binding draft technical assistance documents . . .” and creates significant regulatory uncertainty for air agencies, they oppose the proposal.

#### c. EPA Response

The EPA reiterates that the TADs provide recommendations but are not binding or enforceable and create no obligations on any person. Although the draft TADs are referenced as recommended approaches in the preamble to the proposal and in this final rulemaking, they are not required to be adhered to by any air agency required to characterize air quality around an SO<sub>2</sub> source identified in this rulemaking. The EPA developed the TADs to aid air agencies seeking advice in the air quality characterization process required by this rulemaking. The Agency has indicated that the TADs are meant to be used as possible tools to aid air agencies. This rulemaking does not codify the TADs, and none of the comments on the proposed rule regarding the TADs resulted in changes to the rule itself. The TADs are considered to be living documents that the EPA may update as necessary over time. The Agency believes that a modeling protocol or monitoring network design that follows or references the recommended approaches in the TADs is likely to be adequate, and will better ensure the success and a timely fulfillment of the requirements of this rulemaking. However, air agencies remain free under the final rule to suggest alternative approaches to those suggested in the TADs. Whether an agency chooses to follow a TAD or suggest an alternative approach does not affect the fact that for every approach chosen, the air agency will need to submit their rationale and approach to the EPA for review on a case-by-case basis.

The EPA disagrees with the commenters who claimed that the proposal’s reference to the TADs violates the rulemaking requirements of the Administrative Procedure Act. The Agency did not propose, and is not promulgating language that the TADs are required to be followed, and is not changing their status as non-binding technical assistance documents. In response to the request that the TADs be subjected to notice and comment, in fact the first drafts of the TADs were circulated for review and comment by stakeholders, and revised versions of the TADs were developed in response to those comments.

#### 2. Monitoring and Network Design Issues

##### a. Summary of Proposal

The EPA proposed that air agencies that select the monitoring approach to characterize air quality in an area would have the option to identify appropriate existing monitoring sites, relocate monitors as appropriate or install new monitors, and have them operational by January 1, 2017, in order to provide data for use in the anticipated designations process in calendar year 2020. The EPA proposed to require that any relocated or new monitors be operated either as SLAMS, or in a manner equivalent to those monitors operated elsewhere in the SLAMS network; they do not, however, have to be designated as SLAMS monitors. In the proposal, the EPA stated that the monitors should use Federal Reference Methods (FRMs) or FEMs and meet the requirements of 40 CFR part 58, appendices A, C, and E. Further, the EPA stated that the resulting data should be reported to the Air Quality System (AQS) and would be subject to the same annual data reporting and certification requirements listed in 40 CFR 58.15 and 58.16 as required for SLAMS data. *See* 79 FR 27461, May 13, 2014.

##### b. Brief Summary of Comments

Some commenters suggested that the rule should allow a third party, such as a facility owner, to cover the expenses of siting and operating new monitors in coordination with the air agency. One public interest group commenter stated that there are numerous considerations that make it unlikely that monitors could be sited at ideal modeled locations, including access to the location, power hookups, local pollutant effects and safety from vandalism. Several commenters expressed concern that the lack of clear criteria for designing an SO<sub>2</sub> source-oriented monitoring network puts air agencies in the unreasonable position of designing a monitoring network without knowing whether it will be approved by the EPA.

Some commenters stated that guidance is needed on the number of monitors required. Commenters stated this issue should not be left up to negotiations with the EPA Regional Office; rather, a procedure should be outlined that will provide consistency for all regional offices and air agencies. Some state and industry commenters suggested that one monitor may be sufficient and recommended the final rule include a discussion of the adequacy of one monitor in certain situations. One industry commenter stated that, because large gradients in

design concentrations for SO<sub>2</sub> are likely not present to the extent that the EPA may expect, the use of a single monitor to demonstrate NAAQS attainment is sufficient in many cases.

##### c. EPA Response

The EPA believes that there are no limitations as to who might operate a monitor or monitors being used to satisfy the requirements of this rulemaking. It can be a state, local or tribal government, industry, other third parties or a mix thereof. Whatever the case, the monitor or monitors should be included as a part of the state’s monitoring plan. The critical issue is that the monitor or monitors must be either a SLAMS monitor or SLAMS-like monitor, where the latter might be an industrial or other third party-operated monitor. In either case, the monitor or monitors must be an FRM or an FEM monitor, and must adhere to requirements in 40 CFR part 58, appendices A, C, and E, and adhere to data reporting requirements also contained in 40 CFR part 58. This does require states to provide oversight to any non-SLAMS sites for which they are claiming to satisfy this rulemaking, as the states have the final responsibility to ensure the quality of submitted data that satisfies the intent of this rulemaking.

With respect to concerns over a lack of clear criteria for designing an SO<sub>2</sub> source-oriented monitoring network, the likelihood to appropriately place one or more monitors, and the issue of what number of monitors might be required around a source, there is no one-size-fits-all answer to this question. The EPA indicated in the preamble to the proposal, and in the draft Monitoring TAD, that the relative location and number of monitors that might be sufficient to characterize the air quality around a source is a case-by-case determination. In general, the main objective is to monitor at, or as near as possible to, the location(s) where ambient SO<sub>2</sub> concentration maxima are expected to occur. Site selection for any monitoring network is subject to logistical hurdles including site access, identification or installation of appropriate infrastructure, telecommunications access, and safety, and state, local, and tribal air agencies are well versed in the variety of logistics that can be involved in the installation of an ambient air monitoring station. These issues undoubtedly can play into what any ambient air monitoring network ultimately looks like. However, as is the case with all required ambient air monitoring, responsible air agencies are expected to establish a clear rationale for the number and placement

of the monitors it is using to satisfy the requirements of the rule. In this process, there is flexibility for the state to use professional judgment in determining what is appropriate for their individual situations, but they are expected to perform due diligence in attempting to locate monitors in the most ideal locations possible. Further, the air agency's recommended number of monitors and preliminary rationale should be discussed with the EPA Regional Offices well in advance of the development of an Annual Monitoring Network Plan. As discussed in the Monitoring TAD, the development of a network design and its rationale can be informed by a number of types of analyses which can include the use of air quality modeling, exploratory monitoring, or analysis of existing data. In any scenario, the state would need to have a technically credible rationale that supports the monitoring network design approach that has been chosen to satisfy requirements in this rulemaking.

As stated previously, the TADs provide recommendations for air agencies, but are not binding or enforceable, and they create no obligations on any entity. Although the draft TADs are referenced as providing recommended approaches in the preamble to the proposal and in this final rulemaking, there is no specific provision in this rule that requires the air agency to adhere to the TADs. The TADs have been provided in order to potentially aid air agencies seeking advice in the air quality characterization process required by this rulemaking.

### 3. Areas Failing to Having New Monitors Operational by January 1, 2017

#### a. Summary of Proposal

Where an air agency has chosen the monitoring approach and submitted a list identifying the sources near which air quality is to be monitored, the proposed rule addressed the situation where it becomes evident that sufficient and appropriate monitoring will not be operational in a timely manner. The EPA proposed that the area around the source in question would be functionally "moved" to the modeling pathway, where air quality data characterized by the state under this rule could inform potential future designations that would be intended to occur by December 2017. The EPA requested comment on this approach, and on any alternative approaches that could most effectively address a situation where an air agency is acting in good faith to deploy monitors on time but experiences a delay which may be outside of its control, as well as a

situation where an air agency does not act in good faith to deploy monitors on time. *See* 79 FR 27461, May 13, 2014.

#### b. Brief Summary of Comments

One public interest group commenter stated that the 2017 modeling pathway discussed in the proposal offers a swifter, cheaper, and more accurate way of assessing air quality, and so did not believe that states that missed deadlines along the monitoring pathway should be allowed to further delay designations. Other commenters stated that the fact that modeling is less expensive than monitoring is not a substitute for what they believe is the superior accuracy of actual monitored data; and that they believe the lower costs of modeling do not offset the regulatory costs and other burdens on sources and communities that could result from nonattainment designations based on modeling.

One public interest group commenter stated that because the monitoring approach already could lead to designations occurring a full decade after the NAAQS was promulgated, it should be regarded as an absolute edge-of-the-envelope approach, meaning that failure to meet monitoring deadlines should result in areas being treated under the modeling pathway as a default. This commenter stated that setting such a policy in any final rule would properly incentivize actors to transmit information to the EPA in a timely manner.

A number of state and industry commenters did not agree that a would-be monitored area should be automatically designated at the same time as areas for which the modeling option was chosen in the event of any delay in monitoring. Commenters also stated that the proposed penalty for unanticipated monitoring site delays is excessive and there are too many uncertainties which argue against such automatic actions; especially in cases where the air agency has exercised all due diligence to ensure that the monitors are operational by the deadline in the rule.

#### c. EPA Response

The EPA is clarifying the relationship between this rule and the schedule for promulgating designations under CAA section 107. This rule does not establish any deadlines for designations or prescribe the manner in which future designations would occur. Therefore, it has never been the role of this rule, even as proposed, to promulgate schedules for designations of areas based on whether air agencies timely implement the rule. However, the proposed milestones for implementation of the

rule were devised in consideration of the Agency's preferred and anticipated schedule for completing area designations.

While this rule does not promulgate designation schedules, separate litigation activities have affected the schedule. On March 2, 2015, the U.S. District Court for the Northern District of California issued an order directing the EPA to complete designations pursuant to the schedule discussed earlier in this document. Affected air agencies considering the monitoring option under this rule should be aware of this schedule. Under the terms of the consent decree entered by the court, in order for the EPA to not be required to designate an area by December 31, 2017, air agencies choosing the monitoring option under this rule will need to install and begin operating those monitors by January 1, 2017. This is the date that the rule requires. However, while the rule does not provide designations schedules, and thus does not address how designation schedules would be affected by an air agency missing this deadline, the March 2015 consent decree does. If the monitor is not operational by January 1, 2017, the EPA will not be able to use the future monitoring information to be generated by those monitors in the initial designation for the area, because the court's order allows those designations to occur as late as 2020 only if the monitor is timely installed and operated. Where the January 1, 2017, deadline is not met, the designations must occur by December 31, 2017, and will have to depend upon other information available at that time.

The EPA's proposal addresses circumstances in which an air agency chooses to characterize through monitoring but fails to have monitors become operational on time. The proposal suggests that in these circumstances, the agency (or, for that matter, the EPA) would be required to conduct modeling under this rule and be relieved of further obligations to conduct monitoring, albeit late. The EPA's intent in its notice of proposed rulemaking was to explain that in these circumstances, where an air agency chooses to characterize air quality with new monitors but failed to have the new monitors operational by the January 1, 2017, deadline, the EPA envisioned designating such areas in conjunction with areas being characterized by modeling. That is, the EPA did not envision delaying the designation for such areas to the envisioned 2020 date when the Agency anticipates promulgating designations for areas characterizing air quality through a new

monitoring network. The EPA must now comply with a court-ordered designation schedule, in which the court expressly requires that areas that have not begun operation of a new monitoring network by January 1, 2017, must be designated by December 2017.

Nevertheless, the EPA wishes to clarify that an air agency that chooses monitoring as its means to meet the air quality characterization requirements, and commits in its July 2016 Annual Monitoring Network Plan to conduct such monitoring, remains obligated to fulfill the original requirement to monitor and to provide the resulting air quality characterization around a given SO<sub>2</sub> source, even if operation of new monitors commences after the January 1, 2017, deadline. If a state fails to meet the January 1, 2017, deadline, the state must still meet the monitoring requirements for the area pursuant to 40 CFR part 58, or the EPA may disapprove the state's monitoring plan for the following year, unless, of course, the monitoring plan is revised accordingly. Although, as discussed previously, the EPA will not be able to rely upon the future monitoring data to issue the designation on the court-ordered schedule, the future monitoring data may be useful for other purposes such as tracking progress and making later attainment status determinations needed for redesignations.

#### 4. Monitor Shut Down

##### a. Summary of Proposal

In the preamble, the EPA proposed that a monitor that has been deployed under the monitoring option pursuant to this rule, and is located in an area that is subsequently designated attainment, may be eligible for shut down provided that the monitor meets certain criteria. The EPA proposed in § 51.1203(c)(3) that any SO<sub>2</sub> monitor identified in an approved state annual monitoring network plan to satisfy the rule requirements may be eligible for shut down if the following criteria are met: (1) The monitor is not also satisfying other minimum SO<sub>2</sub> monitoring requirements listed in 40 CFR part 58, appendix D; (2) the monitor is not otherwise required to meet requirements in a SIP or permit; and (3) the monitor has recorded a 3-year design value (DV) that is no greater than 50 percent of the 1-hour SO<sub>2</sub> NAAQS. The EPA also proposed that any SO<sub>2</sub> monitor eligible for shutting down would need to be approved by the EPA Regional Administrator before monitoring operations could cease. As an alternative, the EPA also proposed an option in which the same criteria noted

earlier would need to be met, except that the monitor would be eligible to cease operations if it recorded a design value (DV) in the 3-year period that is no greater than 80 percent of the 1-hour SO<sub>2</sub> NAAQS. The EPA requested comment on the two proposed options for DV criteria for SO<sub>2</sub> monitor shutdown, as well as other potential values within the 50–80 percent range. The EPA requested that commenters provide specific technical rationale supporting any approach they recommend. See 79 FR 27462, May 13, 2014.

##### b. Brief Summary of Comments

Some state and industry commenters agreed with the proposal that monitors placed pursuant to the monitoring option and located in areas that are designated as attainment should be eligible for shut down. Commenters also stated that providing state agencies with the flexibility to shut down unneeded monitors allows agencies to allocate their limited resources more appropriately. One industry commenter stated that, if the sources are properly controlled and/or limited by permit, the risk of significant increases in DVs over time is relatively low absent new sources entering the affected area. Several state and industry commenters supported the proposal, with one state commenter indicating that the use of the 50 percent threshold would be safe to use because the area would require a significant increase in future SO<sub>2</sub> emission to cause an exceedance of the 1-hour SO<sub>2</sub> NAAQS.

Some state commenters recommended that the threshold of 50 percent be dropped in the final rule since 40 CFR 58.14 already contains provisions for shutting down a monitor at 80 percent of the NAAQS. Commenters stated that there does not seem to be a reason to make the criteria more stringent than the existing criteria in 40 CFR part 58 and, if the EPA wishes to change those criteria, a revision to 40 CFR 58.14(c)(1) should be considered and made available for comment. Industry commenters stated that the requirement for annual reporting of changes in SO<sub>2</sub> emissions with the possibility that further monitoring could be required, argues against the more stringent 50 percent option.

Over 25 commenters supported the use of the 80 percent threshold. Commenters stated that 80 percent of the NAAQS is a strong enough criterion for shut down of an SO<sub>2</sub> monitor and the 80 percent criterion is consistent with criteria for shutting down most regulatory monitors. One public interest group commenter stated that new

monitors should not be shut down since (1) short-term monitor readings may not be consistent with long-term attainment and (2) the SO<sub>2</sub> monitor network needs to be rebuilt. In addition, this commenter recommended that monitors not be removed if the concentrations they are recording are trending upward, indicative of potential future problems.

##### c. EPA Response

The EPA is finalizing the rule to allow any SO<sub>2</sub> monitor identified by an air agency in its approved Annual Monitoring Network Plan as having the purpose of satisfying § 51.1203 which is not in an SO<sub>2</sub> nonattainment area, and is not also being used to satisfy other ambient SO<sub>2</sub> minimum monitoring requirements listed in 40 CFR part 58, appendix D, section 4.4, and is not otherwise required as part of a SIP, permit, attainment plan or maintenance plan, to be eligible for shut down if it produces a DV of no greater than 50 percent of the 1-hour SO<sub>2</sub> NAAQS in the first or second 3-year periods of its operation. The EPA has chosen to adopt this shutdown allowance so that those monitors that record DVs that are well below the NAAQS after 3 or 4 years of operation would no longer be required to operate under the unique provisions of this rule, if they are otherwise not required under other requirements. This potential ability to shut down monitors would relieve any resource burden under this rule on air agencies where NAAQS violations have not and likely will not occur. This particular provision will not require estimates of future concentrations as do existing shutdown provisions in 40 CFR 58.14.

More specifically, this monitor shutdown provision works by assessing how two DVs (*i.e.*, one calculated from monitor data collected in years 1 through 3, and one from years 2 through 4) would compare to the 50 percent of the NAAQS shutdown criterion. If a monitor produces a DV from data collected in years 1 through 3 that is no greater than 50 percent of the NAAQS, it is eligible for shutdown if it is not otherwise required to operate. If the DV is above the 50 percent threshold, the monitor must continue operation. If that monitor produces a DV no greater than 50 percent of the NAAQS from data in years 2 through 4, it is eligible for shutdown if not otherwise required to operate. If, instead, the DV is again above the 50 percent threshold, the air agency must continue to operate the monitor. From that point forward (*i.e.*, for data collection year 2021 and beyond), the applicable monitor shutdown provisions are those that exist in 40 CFR 58.14, which include

probabilistic estimations of future concentrations and other circumstantial situations that might allow for monitor shutdown.

The Agency would like to note language of particular relevance from 40 CFR part 58 regarding eligibility for shutdown based on recorded data and calculated design values that exists in § 58.14(c)(1). This particular provision allows monitoring discontinuation with the Regional Administrator approval for: “Any PM<sub>2.5</sub>, O<sub>3</sub>, CO, PM<sub>10</sub>, SO<sub>2</sub>, Pb, or NO<sub>2</sub> SLAMS monitor which has shown attainment during the previous 5 years, that has a probability of less than 10 percent of exceeding 80 percent of the applicable NAAQS during the next 3 years based on the levels, trends, and variability observed in the past, and which is not specifically required by an attainment plan or maintenance plan. In a nonattainment or maintenance area, if the most recent attainment or maintenance plan adopted by the state, and approved by the EPA, contains a contingency measure to be triggered by an air quality concentration and the monitor to be discontinued is the only SLAMS monitor operating in the nonattainment or maintenance area, the monitor may not be discontinued.”

In any circumstance regarding monitor shutdown, whether pursuant to this final rule or 40 CFR part 58, the air agency must receive the EPA Regional Administrator approval of a request to cease operation of the monitor as part of its action on the annual monitoring plan under 40 CFR 58.10 prior to the shutdown of any qualifying monitor. Therefore, under the final rule, there are two sequential routes for possibly shutting down a monitor. If a monitor shows DVs greater than 50 percent of the NAAQS after the first two 3-year periods of its operation and cannot be approved for shut down under the first sequential route, the monitoring will continue. However, after 5 years of operation it can be considered for shutdown if it meets the criteria that the EPA's rules at 40 CFR 58.14(c)(1) apply, with the EPA Regional Administrator's approval. These monitors might also be subject to shut down eligibility as set forth in § 58.14(c)(2), (3), (5), and (6).

#### 5. Annual Reporting Following Monitor Shutdown

##### a. Summary of Proposal

For any area for which the EPA has approved an air agency's request for an SO<sub>2</sub> monitor to cease operations, the EPA proposed that the air agency be required to assess SO<sub>2</sub> emissions changes annually, beginning in the year after the monitor ceases operation. (The

proposal contained a similar requirement for modeled areas, discussed later in this section.) For areas around these sources in which total SO<sub>2</sub> emissions increase over the emissions for the previous year, the EPA proposed that the air agency would be required to submit to the EPA an assessment of the cause of the increase and provide an initial determination of whether the air quality around that source should be further re-assessed. The EPA proposed that the air agency could choose to reinstate the operation of the air monitor or complete air quality modeling for the source area to verify that the area continues to attain the standard. In the proposal, the EPA stated that, if modeling or monitoring information required to be submitted by the air agency to the EPA pursuant to § 51.1205 indicates that an area is not attaining the 2010 SO<sub>2</sub> NAAQS, the EPA may take appropriate action, including but not limited to disapproving the monitoring plan, requiring adoption of enforceable emission limits to ensure continued attainment of the 2010 SO<sub>2</sub> NAAQS, redesignation of the area to nonattainment, or issuance of a SIP Call.

The EPA proposed two options for how the air agency would submit this report and how the EPA would review and act on it. Under the first option, the EPA proposed that the air agency would submit a report to the EPA annually as an appendix to the air agency's annual monitoring plan; the annual monitoring plan is required to be submitted to the EPA Regional Administrator by July 1st each year. In the proposal, the EPA stated that the inclusion of this verification report as an appendix to the annual monitoring plan would ensure that the report would be subject to public review and comments that are to be provided for the monitoring plan pursuant to regulations at 40 CFR 58.10.

Under the second option, the annual report of emissions data for sources for which the state ceased the operation of nearby monitors would be submitted to the EPA in the form of a separate, independent annual submittal from the state to the EPA Regional Administrator due by the same July 1st date each year. This independent submittal would follow the general guidelines set forth in 40 CFR 58.10 regarding opportunities for public review and comment as described in Option 1, but the report would only include the annual assessments associated with sources in areas that were designated unclassifiable/attainment and for which the EPA granted approval to cease monitoring. The EPA invited comment on any suggested alternatives to these

procedural options. *See* 79 FR 27462, May 13, 2014.

##### b. Brief Summary of Comments

Several state and industry commenters stated that the proposed annual reporting requirement appears to be unduly burdensome. Some industry commenters opposed the annual reporting requirement, stating that SO<sub>2</sub> emissions from sources are already available to the EPA and the need for ongoing data requirements has not been demonstrated. One state commenter suggested that, if the monitors that were removed were providing data under 50 percent of the standard, there is no reason to perform such analyses since an increase in emissions that would result in such a drastic increase in monitored design values would surely be associated with changes to operations that would necessitate air permitting, which evaluates projects for NAAQS compliance.

One group of state commenters stated that the EPA's proposed July 1st submittal date is unrealistic because states will not have the required quality-assured emissions monitoring data processed by July 1st. Some state and industry commenters recommended a less burdensome process in which this verification would take place every 3 to 5 years instead of annually, pointing out that the EPA publishes the NEI data every 3 years, the EPA reviews the NAAQS every 5 years, and there is a 5-year ambient monitoring assessment plan required by 40 CFR 58.10.

Commenters requested clarification regarding the determination of an emissions increase. One state commenter stated that it is unclear whether an emission increase should be based on an increase greater than the 3 year average of emissions during the initial monitoring analysis, an increase above the highest single year of emissions during the initial monitoring analysis, or some other metric. Some commenters recommended the comparison be based on some compliant level of emissions from the year(s) where the monitor demonstrated attainment with the standard, since the “increase” or “decrease” in emissions of SO<sub>2</sub> may have resulted in total SO<sub>2</sub> emissions levels well below the annual emission rates during the years when monitoring data showed compliance.

One tribal and several state commenters supported the option of including the annual emissions analysis with the annual monitoring plan. One commenter stated that the analysis of emissions is closely related to network planning, and this procedure would provide a single document for public

inspection and EPA review and approval. Another commenter stated that the annual monitoring plan may not be the best tool or location to place modeled data, emission reports, ongoing data requirements, and requests to cease modeling. Other state commenters recommended that the monitoring plan verification report be considered a separate element for ease of processing and for public review.

#### c. EPA Response

The EPA has decided not to finalize the proposed requirement that any state with an area for which the EPA has approved the air agency's request for an SO<sub>2</sub> monitor to cease operations must still assess SO<sub>2</sub> emissions changes annually, beginning in the year after the monitor ceases operation. The EPA made this decision based upon comments on the proposed rule, and in recognition that a cessation of monitoring will not occur unless a monitor has measured SO<sub>2</sub> concentrations well below the NAAQS for a given time period and an EPA Regional Administrator has allowed the shut-down. The Agency is persuaded by commenters that monitor shutdown provisions, along with generally applicable emissions reporting requirements, are of sufficient strength that subsequent additional annual observation and reporting of SO<sub>2</sub> source emissions profiles by states specifically due to this rulemaking is unnecessary. Further, there are means by which monitoring can be reinitiated in the future if the unlikely scenario occurs where SO<sub>2</sub> emissions rise significantly in an area, or other data indicate possible NAAQS violations in an area after a monitor has been shut-down, mainly through the EPA Regional Administrator authority granted in 40 CFR part 58, appendix D, section 4.4.3.

#### 6. Modeling Issues

##### a. AERMOD

##### i. Summary of Proposal

In the proposal, the EPA stated that the Agency anticipates that in implementing the rule air agencies would likely use AERMOD to conduct modeling, as AERMOD is the EPA's preferred near-field dispersion model and has been demonstrated to be a reliable predictor of SO<sub>2</sub> air quality given appropriate input data. The EPA explained in the proposed rule that, as part of its development, AERMOD was evaluated using 17 field studies, several of which involved short-term measurements of SO<sub>2</sub>, robust site-specific meteorology and accurate measurements of emissions. The EPA

stated in the proposal that the Agency is confident that AERMOD can provide accurate predictions of actual SO<sub>2</sub> concentrations given representative meteorology and accurate emissions inputs. *See* 79 FR 27463, May 13, 2014.

##### ii. Brief Summary of Comments

One industry commenter stated that, for certain conventional SO<sub>2</sub> emission scenarios, such as tall stacks at coal fired EGUs, AERMOD can be at least reasonably predictive. One public interest group commenter stated that AERMOD modeling performs particularly well in evaluating emission sources with one or a handful of large emission points. This public interest group commenter cited a declaration of Roger W. Brode (EPA) filed in the EPA's successful defense of the 2010 SO<sub>2</sub> NAAQS in which he stated that AERMOD is capable of accurately predicting whether the revised primary SO<sub>2</sub> NAAQS is attained and whether individual sources cause or contribute to a violation of the SO<sub>2</sub> NAAQS. This commenter also stated that AERMOD has been tested and performs very well during conditions of low wind speeds, citing comments of Camille Sears.

A number of commenters expressed concern with the use of AERMOD. Some commenters stated that AERMOD was intentionally designed to over-predict SO<sub>2</sub> concentrations. Several commenters referenced studies that indicate AERMOD over-predicts, including studies by the Electric Power Research Institute (EPRI), AECOM and some air agencies. Commenters identified a number of issues that they believe need to be addressed because they lead to over-predicting SO<sub>2</sub> concentrations, including buoyant line sources, building downwash, conservative assumptions in terms of model input, modeling of multiple sources, periods of low wind speed, steep terrain and lack of representative meteorological data. Commenters stated that the individual aspects of AERMOD and the EPA's guidance that contribute to over-prediction of the SO<sub>2</sub> concentrations in the context of the 1-hour NAAQS are multiplicative.

##### iii. EPA Response

In this final rule, the EPA is not promulgating a requirement that air agencies use AERMOD in all cases, but is retaining the existing flexibility otherwise provided by the EPA's rules for agencies to support the use of the best model for a particular case. The EPA's latest recommendations for making this assessment are contained in the Modeling TAD. In most cases, the EPA believes that AERMOD will likely

be the model of choice by air agencies to address the requirements of this rule, unless the application involves a different recommended model, such as the Buoyant Line and Point Source Dispersion Model (BLP). Models recommended for particular applications are listed in appendix A of the EPA's Guideline on Air Quality Models.<sup>10</sup> Section 3.2 of the EPA's Guideline on Air Quality Models outlines the procedures for use of alternative models for those cases where an alternative model may be more appropriate than a preferred model. In addition, the Modeling TAD also discusses past use of alternative models for particular applications.<sup>11</sup> The EPA recommends consultation with the appropriate reviewing authority or EPA Regional Office to determine if the use of an alternative model is valid for that application.

In addition, as stated previously, the TADs are documents that provide recommendations but are not binding or enforceable and create no obligations on any person. Although the draft TADs are referenced as recommended approaches in the preamble to the proposal and in this rulemaking, they are not required to be adhered to by any state who is required to characterize air quality around an SO<sub>2</sub> source identified in this rulemaking. The TADs have been provided in order to potentially aid air agencies seeking advice in the air quality characterization process required by this rulemaking.

With regards to concerns regarding model conservatism, EPA recently proposed updates to AERMOD to address concerns regarding buoyant line sources, building downwash, and low wind speed issues. *See* 80 FR 45340 July 29, 2015. With regards to comments about model inputs that lead to over-estimates, as part of its development, AERMOD has been shown to perform well against observed concentrations when actual emissions have been used. The modeling of actual emissions for multiple sources is not anticipated to cause over-predictions. The modeling TAD also discusses that the number of sources explicitly modeled in an

<sup>10</sup> Revision to the Guideline on Air Quality Models: Enhancements to the AERMOD Dispersion Modeling System and Incorporation of Approaches to Address Ozone and Fine Particulate Matter" can be found at <http://www.epa.gov/ttn/scram/11thmodconf.htm>.

<sup>11</sup> It is the EPA's intention to update the Modeling and Monitoring TADs as necessary to reflect any change in policy or to make clarifications that are necessary. Therefore, any comments on the TADs themselves that have been submitted in response to the proposed rule will be addressed as a part of any updates made to the TADs in the future, rather than in this final rule.

application is expected to be low and that in many cases, a number of sources in a modeling domain can be represented by background concentrations instead of being explicitly modeled, thus reducing potential overestimates in modeling.

#### b. Emissions Data

##### i. Summary of Proposal

The EPA proposed that modeling analyses be based on either actual 1-hour SO<sub>2</sub> emissions from the most recent 3 years or federally enforceable allowable emissions. The EPA referred readers to the Modeling TAD for a more detailed discussion of a range of recommended options for determining actual emissions. While actual emissions would be the preferred choice to use for emissions inputs, air agencies have the option of using a more conservative approach by inputting a source's most recent 3 years of allowable, or "potential to emit," emissions. Additional information and recommendations on this approach are discussed in the Modeling TAD. *See* 79 FR 27446, 27464, May 13, 2014.

##### ii. Brief Summary of Comments

More than 30 state and industry commenters supported statements in the EPA's proposal that allow the use of actual emissions as an input in the air quality modeling in order to most effectively serve as a surrogate for comprehensive ambient monitoring results. Several commenters suggested that the use of allowable emissions as an input to air quality modeling analyses would result in modeled air quality values that were higher than air quality levels that would be expected to be observed by a properly sited ambient monitor. Commenters stated that using actual emissions is even more important when conducting a cumulative impact analysis (assessing potential impacts from two or more sources) since the model's tendency to overestimate ambient air impacts is compounded when numerous sources are all modeled at peak emissions at all times.

Several state and industry commenters supported the EPA's proposal to base the modeling analyses on actual emissions over a 3-year period. One commenter noted that, in situations where multiple sources are being modeled, the most recent 3 years of actual emissions data may not be the same for all sources, particularly if there is a mix of EGUs and non-EGUs. One state commenter suggested that, if justification can be provided for an alternative dataset, it too may be considered for modeling. One state

commenter recommended the rule clarify that states must use the most recent 3 years of emissions data that are available at the time that a modeling protocol for that area is submitted to the EPA, and that revised modeling should not be required if more recent emissions data become available.

##### iii. EPA Response

When using actual emissions, the EPA believes the most recent 3 years of time varying emissions (e.g., emissions that vary hourly, seasonally, monthly, daily, etc.) should be modeled since the air quality modeling is being used as a surrogate for monitoring. The Modeling TAD gives recommendations on inputting hourly emissions into AERMOD for those sources with hourly continuous emissions monitoring (CEM) data and also gives recommendations on inputting time varying emissions (e.g., seasonally, monthly, etc.) when no hourly emissions are available and only annual emissions and data such as production logs or fuel usage are available. However, the final rule does not restrict the ability of air agencies to use more conservative allowable emissions in conducting their modeling. In the event that a particular source does not have the most recent 3 years actual of emissions, it may be possible to use the most recently available emissions or develop the most recent 3 years of emissions using recommendations in the Modeling TAD. The reviewing authority should work with the appropriate EPA Regional Office on the use of such emissions. For an application that contains a mix of sources whose emissions data are not concurrent with each other, it is possible to model all of these sources together following recommendations in the Modeling TAD. Once a modeling protocol or modeling analyses have been submitted, there is no requirement to revise the protocol or modeling respectively if more recent emissions have become available since the submission, and in the best professional judgment of the reviewing authority, those emission changes do not warrant a revision to the protocol or modeling analyses.

#### c. Accounting for Recent Emission Reductions in Modeling Analyses

##### i. Summary of Proposal

In the proposal, the EPA noted that, in some cases, air quality modeling conducted in advance of January 2017 may indicate a violation of the 1-hour SO<sub>2</sub> standard and, to address such situations, the air agency may wish to consult with the source(s) and take

action to adopt enforceable emissions limitations as necessary prior to January 2017 to potentially avoid a nonattainment designation. The EPA proposed that, as long as these controls are implemented and enforceable as of January 2017, it would be appropriate for the new lower allowable emissions to be used in the modeling analysis in place of the higher actual emissions.

The EPA proposed that, if the air agency is able to demonstrate attainment with the new controls or emission limits, the governor of the state has the opportunity to modify its designation recommendation accordingly, if that designation has not yet been issued. *See* 79 FR 27464, May 13, 2014.

##### ii. Brief Summary of Comments

A number of commenters supported the inclusion of language providing the option for states to model more recent emission rates based on enforceable limits implemented in advance of the January 2017 modeling deadline. Commenters stated that this approach is a reasonable option which would provide industry with an incentive to achieve timely emission reductions to meet the regulatory requirements while potentially relieving air agencies from the requirements that a nonattainment designation entails, if such a designation has not yet been issued. One industry commenter requested that the method for reducing emissions not be limited to installing controls.

Some state commenters requested that the EPA develop methodologies for air agencies to work with sources whose 2015 emissions are above the threshold to establish permanent and enforceable emission limitations that show attainment with the SO<sub>2</sub> standards prior to a designation of such sources' areas. One state commenter stated that there must be a process that allows for the air agencies' discretion under extenuating circumstances in order to account for significant changes at a facility that occurred during the most recent 3 years.

##### iii. EPA Response

After review of the comments, the EPA continues to believe that it is appropriate for the air agency to consult with the affected source(s) and take action to adopt enforceable emissions limitations as necessary prior to January 2017. As long as the emissions limitations are in place and enforceable by January 2017, the new allowable emission limit may be input into the model instead of the actual emissions of the most recent 3 years.

The EPA expects that a number of emissions sources may be candidates for this optional approach. Many EGUs

were subject to compliance deadlines for the MATS in April 2015 (or in some cases are subject to April 2016 deadlines), and the EPA expects that many will become subject to title V permits that require compliance with MATS SO<sub>2</sub> emission limits as the means of demonstrating compliance with the MATS requirements related to acid gas emissions. These EGUs may be able to adopt control technologies and enforceable emission limits to reduce emissions of SO<sub>2</sub>, as well as mercury. Similarly, industrial boiler operators will have the incentive to adopt SO<sub>2</sub> emission limits as part of their strategy for complying with the Industrial Boiler Maximum Achievable Control Technology Standard. 78 FR 7162, January 31, 2013.

Therefore, the EPA believes that as long as these emissions reductions are implemented and enforceable by to January 2017, it would be appropriate for the new lower allowable emissions to be used in a modeling analysis in place of the higher actual emissions. The air quality impacts from such a source would be characterized by the new enforceable allowable limit and could be used as a basis for future determinations regarding areas' attainment status.

#### d. Stack Height

##### i. Summary of Proposal

The EPA described its view in the proposed rule that actual stack height is appropriate to use in conjunction with actual emissions in a modeling approach to characterize current air quality. The EPA also described its view that, if an air agency chooses to use allowable emissions, then it should use good engineering practice (GEP) stack height when the actual stack height exceeds the GEP height because the GEP height is used when calculating the allowable emission rates. The EPA noted that additional recommendations on the use of actual stack height can be found in the Modeling TAD. *See* 79 FR 27464, May 13, 2014.

##### ii. Brief Summary of Comments

A number of state and industry commenters supported the EPA's views on the use of actual stack height in conjunction with actual emissions. However, several state and industry commenters did not agree that GEP stack height should be used if a state chooses to use allowable emissions. Commenters stated the EPA should allow sources to model using actual stack height regardless of whether they are modeling actual emissions or allowable emissions since the purpose

of the rule is to estimate, as accurately as possible, conditions that would be measured at a monitor. Commenters also stated that GEP stack height is not always a factor in establishing the emissions limit, where such limits are not established under an implementation plan subject to the restrictions of CAA section 123; for example, in the context of emission limits that are established based on emission standards under CAA section 112, such as the MATS rule. One commenter stated that the concern about giving inappropriate credit for dispersion techniques is irrelevant in the context of this designation modeling as CAA section 123 applies only to emission limitation controls.

##### iii. EPA Response

After consideration of comments, the EPA continues to recommend the use of actual stack heights when using actual emissions and the use of GEP height when modeling with allowable emissions where such emissions limits are or would be subject to CAA section 123 and to the EPA's corresponding regulations implementing GEP requirements. This would include limits established under any CAA provision that are intended to be credited in an implementation plan for attaining and maintaining the NAAQS. The use of GEP for allowable emissions modeling in such situations is based on the fact that the modeling conducted to determine the emissions limits was or would be based on GEP stack heights. Therefore, if actual stack heights (when above GEP) were used in such situations, the behavior of the modeled sources would not be consistent with the modeling results used to determine the emissions limits relied upon to demonstrate attainment of the NAAQS.

#### e. Meteorological Data

##### i. Summary of Proposal

For purposes of conducting modeling that simulates what might be expected to be measured by an ambient monitor, the EPA recommended the use of 3 years of meteorological data. The EPA stated that, ideally, air agencies would use the most recent 3 years of meteorological data and the same 3 years of actual emissions data when modeling for designations. The EPA noted that the Modeling TAD has additional suggestions on these meteorological inputs. *See* 79 FR 27465, May 13, 2014.

##### ii. Brief Summary of Comments

Some commenters recommended the use of 1 year of meteorological data rather than 3 years and provided several

reasons: Use of 1 year of on-site meteorological data would yield a very robust data set; 3 years does not provide a significant benefit over 1 year; 1 year of meteorological data is sufficient for PSD purposes; collection of 3 years of data would delay the running of AERMOD; and collection of 3 years of data would be unnecessarily expensive. Commenters stated that, while relatively few meteorological databases with 3 years of on-site meteorological data exist, many sources may have previously collected a full year of data and should be able to use that data without starting all over again on an expensive 3-year effort. One state commenter asked the EPA to clarify what is meant by "the most recent 3 years."

One state commenter recommended that up to 5 years of meteorological data be used and stated that, while a single 3-year period may not provide adequate confidence in the analysis, 5 years will provide more 3-year combinations that can be compared to the NAAQS, and more meteorological data improves confidence in the result. Some commenters requested that the EPA clarify:

- That air agencies need not use concurrent meteorological data, given that some sites simply do not have concurrent meteorological data.
- Given the lack of 3 years of on-site data in many areas, the EPA should approve the use of prognostic meteorological data.

##### iii. EPA Response

The EPA's recommendation is to use the most recent 3 years of representative site-specific data or when site-specific data are not readily available, or it is not feasible or cost-effective to collect site-specific data, the most recent 3 years of representative National Weather Service meteorological data or other representative data. When the most recent 3 years of representative meteorological data are not available, the use of older representative meteorological data can be used. For such cases, the Modeling TAD offers recommendations on synching the older meteorological data with the more recent emissions, especially for those sources utilizing hourly emissions. The Modeling TAD provides an explanation of the need for 3 years of meteorological data, even if only 1 year of on-site meteorological data are available. With regards to the type of meteorological data that are available, *i.e.* site-specific, NWS data, or prognostic data, the EPA's Modeling Guideline should be consulted on the latest acceptable forms

of meteorological data at the time of the modeling analyses.

f. Modeling Protocol, Including Multiple Sources

i. Summary of Proposal

This rulemaking proposed that each state list the sources that are to be addressed under this rule and the approach to be used to meet this rule's requirements (air quality characterization through monitoring, air quality characterization through modeling, or establishment of a requirement for a timely source shutdown) for each source. In preparation for conducting modeling, the EPA proposed that the state would need to develop a modeling protocol for all the sources the state plans to model. Specifically, in § 51.1203(d), the EPA proposed that the air agency consult with the appropriate EPA Regional Office in developing modeling protocols and submit the protocol to the Regional Administrator for review. In § 51.1203(d)(1), the EPA proposed that the modeling protocol shall include information about the modeling approach to be followed, including but not limited to the model to be used, modeling domain, receptor grid, emissions dataset, meteorological dataset and how the state will account for background SO<sub>2</sub> concentrations. The EPA stated that details on the suggested protocol elements and the recommended standard format of this protocol can be found in the Modeling TAD. *See* 79 FR 27465, May 13, 2014.

ii. Brief Summary of Comments

Some state and industry commenters requested that the EPA provide more specific guidance on conducting multi-source modeling analyses. Commenters stated that leaving these topics for negotiation with the EPA Regional Office will lead to inconsistent application of guidance among states. Commenters requested guidance on when a source should be modeled by itself, when a source should be modeled with other sources in the surrounding area, more detail on the size and location of sources that should be included in a multi-source analyses, and who would be responsible for conducting analyses when sources are located in multi-state areas. One state commenter requested that guidance on modeling facilities across state lines should be addressed.

iii. EPA Response

The determination of whether to include nearby sources in a modeling exercise around a source that exceeds the emissions threshold is case specific,

and a standardized methodology cannot be developed to fit all scenarios.

Therefore, the final rule does not promulgate requirements addressing nearby sources. The EPA has offered technical recommendations in the Modeling TAD. The identification of nearby sources for modeling should rely on sound technical reasoning and best professional judgment. The EPA emphasizes that not all emissions sources near the source of interest need to be explicitly modeled, as in some cases the impacts of those sources can be sufficiently represented by a background monitor as discussed in the Modeling TAD and section 8.2 of the EPA's Modeling Guideline.

As stated previously, the TADs provide recommendations but are not binding or enforceable and create no obligations on any person. Although the draft TADs are referenced as recommended approaches in the preamble to the proposal and in this rulemaking, they are not required to be adhered to by any air agency who is required to characterize air quality around an SO<sub>2</sub> source identified in this rulemaking. The TADs have been provided in order to potentially aid air agencies seeking advice in the air quality characterization process required by this rulemaking. The Agency has indicated that the TADs are meant to be used as possible tools to aid air agencies. The EPA is not codifying changes to the TADs in this rulemaking in response to any comments received on the proposed rule. The TADs are living documents which the EPA may update as necessary.

g. Ongoing Air Agency Data Requirements for Areas That Were Initially Modeled

i. Summary of Proposal

The EPA proposed that, for areas with modeled air quality data based on actual emissions that did not exceed the standard, air agencies would be required to continue to submit information to the EPA in subsequent years that provide a reasonable assurance that the area continues to have air quality that does not exceed the standard. The EPA proposed three options for how air agencies that rely on modeling of actual emissions would need to conduct additional emissions and/or modeling analyses. In the proposed rule, the EPA believed that such additional analyses would only be needed for areas that had been designated as "unclassifiable/attainment" based on actual emissions-based modeling. The EPA further noted in the proposed rule that modeled source areas would not be subject to

these ongoing data requirements if (1) modeling for the source was conducted using allowable emissions, or (2) the modeling for the source was conducted using actual emissions and the relevant sources then adopted enforceable emission limits consistent with the actual emissions rates used in the modeling.

In Option 1, the EPA proposed that any air agency that will be subject to an ongoing data requirement for modeled areas would be required to assess the most recent SO<sub>2</sub> emissions data annually, beginning in the year after the area is designated as unclassifiable/attainment, and to conduct updated air quality modeling every 3 years, and in additional years when the air agency or the EPA determines that such modeling is warranted. Air agencies would be able to request that the EPA Regional Administrator approve a suspension of the triennial modeling requirement for an area if their most recent modeling DV was less than 50 percent of the NAAQS.

In Option 2, the EPA proposed to require the air agency to provide the EPA with an assessment of SO<sub>2</sub> emissions changes for each source annually, as in Option 1, but to not have a requirement to conduct updated air quality modeling every 3 years. For sources for which the air agency determines that emissions have increased, the air agency would be required to submit to the EPA an assessment of the cause of the increase, and provide the EPA with an initial determination of whether air quality modeling would be needed to verify that the area around the source continues to have air quality levels that do not exceed the standard. If the air agency or the EPA determines that additional air quality modeling is necessary, the air agency would be required to submit the results of that assessment in a timely fashion—within 12 months.

In Option 3, the EPA proposed to require the state to perform periodic screening modeling every 3 years for all source areas that had been previously modeled and determined to be attaining the standard, and submit such modeling for review to the EPA. Screening modeling is commonly performed using a set of default parameters rather than area-specific parameters, and it generally simulates air quality levels that are more "conservative" than levels that would be estimated using area-specific parameters. In the proposal, the EPA stated that a complete, full-scale modeling analysis with updated emissions and meteorological inputs would only be required if the state performs screening modeling that indicates a potential violation. Under all

three options, if the modeling performed indicates that air quality levels in an area exceed the SO<sub>2</sub> NAAQS, the EPA may take any appropriate action, including, but not limited to, requiring adoption of enforceable emission limits to ensure that future air quality levels in the area do not exceed the SO<sub>2</sub> NAAQS; redesignation of the area to nonattainment; or issuance of a SIP call requiring action by the state to bring the area into attainment.

The EPA requested comment on these three options for ongoing data requirements for air agencies with sources modeled based on actual emissions, and requested that each commenter provide a clear rationale for their position. The EPA also invited comments on any alternative ideas and asked that the commenter provide a detailed rationale and estimate of any associated costs for any such recommendations. *See* 79 FR 27465, May 13, 2014.

#### ii. Brief Summary of Comments

Several state, environmental, and tribal commenters supported Option 1. These commenters stated that an approach that simply assesses SO<sub>2</sub> emissions changes at large sources would not account for variations in meteorological conditions, increased SO<sub>2</sub> emissions from interactive sources, or improvements to the actual modeling computer program. One commenter stated that annual modeling makes far more sense from the perspective of protecting the public health, and suggested that modeling once every 3 years is an extremely periodic and slow way of assessing air quality, such that people living in the impacted area could be unaware for years, and thus unable to take action to protect themselves or place pressure on their government to correct the problem.

Several state and industry commenters opposed Option 1 and stated that modeling assessments should not be conducted on a 3-year or any other regular basis. Some believed the requirement to model every 3 years would be an inefficient use of resources and arbitrary since it would not take into account information which might show that undergoing a revised modeling analysis would be unnecessary. They claimed that as long as conditions have remained the same or possibly improved in the intervening timeframe, additional modeling will provide no additional useful information. Others opposed Option 1 on the grounds that no other ambient standard requires such a detailed ongoing analysis. Consistent with their concerns about resources, commenters

supported the aspect of Option 1 that would enable the air agency to terminate certain ongoing data requirements if air quality modeling indicated a DV equal to or less than 50 percent of the 1-hour SO<sub>2</sub> NAAQS.

A number of state and tribal commenters objected to Option 2. One tribal commenter stated that the proposed emissions assessments required in Option 2, which lack a regular air quality modeling requirement, are not stringent enough. Some state commenters expressed concern that this option could lead to an indeterminate number of future analyses required, and that such open-ended requirements have cost implications that could strain states' already-limited resources. On the other hand, more than 20 state and industry commenters supported Option 2 because it balances providing air quality protection with level of effort from state regulatory authorities. Several commenters noted that with SO<sub>2</sub> emissions declining on a national level, remodeling would not be expected to be required and a simple analysis of the change in emissions would be sufficient to determine the need for additional modeling. A state commenter suggested providing clearer guidance regarding what level of emissions increase would trigger further evaluation of sources, rather than having the air agency provide an assessment for each source with increased emissions. The commenter suggested (1) if the original modeling level was equal to or greater than 90 percent of the standard, then new modeling would be required for the area in the event there is any increase in emissions in the area; (2) if the original modeling level was between 50 percent and 75 percent of the standard, then new modeling would be required for the area if area emissions increased by 15 percent or more; and (3) if the original modeling level was less than 50 percent of the standard, then the ongoing modeling requirement should not apply (similar to the provision in Option 1).

Another state commenter stated that, ideally, under Option 2, agencies would have a 2.5-year timeframe to complete the entire ongoing data requirement process: The first year would consist of preparing and submitting data for the national emissions inventory for the previous year; 6 months thereafter agencies would submit a report to the EPA stating whether air quality modeling is needed; and 12 more months would then be permitted to perform any additional modeling deemed necessary.

Regarding Option 3, several state and industry commenters disagreed with

having any default modeling requirement, even for screening modeling, and opposed this option. Several commenters objected to the required use of a screening model for the following reasons: Most of the facilities will have multiple emission points and the screening tools were not designed to evaluate such complex situations; the mandatory use of screening models will result in an overly cautious, ineffective approach to verification; and screening modeling is almost as complex and time consuming as full-scale modeling and thus this option would not be a good use of state and the EPA resources.

Lastly, some commenters suggested that the air agency should be able to choose which ongoing data requirement approach it intends to follow for a particular area. Another commenter suggested an approach that would be a combination of all three options, where the air agency would evaluate emissions changes each year, and then conduct screening modeling or full-scale modeling if the magnitude of emission changes warrant.

#### iii. EPA Response

The EPA recognizes the concerns of commenters about the resource considerations associated with Options 1 and 3, which for areas with modeling based on actual emissions and designated as attaining would require full-scale modeling or screening modeling every 3 years, even if annual emissions in the area were not increasing. We disagree with those commenters who oppose any requirement for ongoing data assessment at all; and with those commenters who suggest a requirement for annual modeling for all areas. The EPA believes that a reasonable requirement for ongoing evaluation of priority areas identified by this rule is important to meeting the public health objectives of this NAAQS while balancing resource constraints of air agencies in a manageable way. The EPA agrees with commenters that suggest it would be reasonable to check emissions changes first, and based on that information, then make a determination about whether to conduct additional modeling. The EPA is also mindful of the fact that in this rule, modeling is effectively serving as a surrogate for monitoring, and so the EPA believes it is reasonable to have similar approaches for terminating the ongoing data requirements for both areas where air quality was initially characterized by monitoring, and areas where air quality was initially characterized by modeling.

After considering the comments received on the proposed rule, the EPA is finalizing a combination of elements from Option 1 and Option 2. As outlined in proposed Option 2, the final approach requires the air agency to conduct an assessment of emissions changes annually for all source areas for which the initial air quality modeling was based on actual emissions and the area was designated as attaining the standard. The air agency must provide this assessment to the EPA in the form of a report, to be submitted by July 1 of the following year. This assessment should reflect the most recent quality-assured emissions data available for the relevant sources in the area. The report must also describe the reason for emissions increases in the previous year at any listed sources, and must include a recommendation indicating for which sources and areas the emissions increase was substantial enough to warrant updated air quality modeling that would help determine air quality levels relative to the standard.

Adapting suggested criteria from a state commenter (with some modification), the EPA recommends as a general guideline that the air agency should conduct additional modeling (using the most recent actual emissions as inputs) for an area if (1) the original modeling level was equal to or greater than 90 percent of the standard, and there is any increase in emissions in the area; or (2) if the original modeling level was between 50 percent and 90 percent of the standard, and emissions in the area increased by 15 percent or more. However, the EPA is not promulgating specific criteria for when additional modeling is required because the EPA believes that the need for additional modeling is best judged on a case-by-case basis reflecting case-specific information on emissions changes and prior modeling results. For example, if the emissions increase was substantial and the previous modeling had indicated that air quality in the area was just under the standard, then air quality modeling would be warranted. In other cases where air quality has been modeled to be well below the standard and annual emissions increase only slightly in the following year, the air agency would be able to exercise judgment regarding whether additional modeling would be needed. The use of case-specific judgment will be especially important in cases involving multiple sources or multiple emission units that may have different emissions-air quality relationships.

The modeling analysis for the area would then be due within 12 months of the air agency recommendation that

such modeling is warranted (*i.e.* by July 1 of the following year). In this way, if new modeling is recommended, the whole process ideally would take 18 months from the end of the “ongoing data requirement” year to when new modeling would be due (not 30 months as suggested by a state commenter).

The EPA finds that the relatively straightforward approach described in proposed Option 2 requiring the examination of emissions data annually (rather than conducting updated air quality modeling every 3 years for every area) is consistent with the frequency with which ambient monitoring data is evaluated. This approach also provides some flexibility to the air agency in recommending whether the magnitude of emissions changes in an area would be large enough to warrant new modeling. As compared to Options 1 and 3, this approach also would be expected to involve less overall workload for air agencies over time.

In addition, as provided in Option 1, the final rule also includes a provision in § 51.1205(b) enabling the air agency to terminate the ongoing data requirement for a modeled area if it meets certain criteria. The provision is analogous to § 51.1205(a), which allows for the air agency to obtain EPA approval to cease operation of a new ambient monitor if the most recent DV is low enough to meet certain criteria (*e.g.* less than or equal to 50 percent of the level of the NAAQS, or meeting the criteria of 40 CFR 58.14). Thus, for areas that were originally modeled based on actual emissions, § 51.1205(b) of the rule allows termination of the air agency’s annual emission reporting requirement if the air agency submits an air quality modeling analysis, using updated actual emissions data from the most recent 3 years, that demonstrates that air quality DVs at all receptors in the analysis are less than or equal to 50 percent of the 1-hour SO<sub>2</sub> NAAQS, and such demonstration is approved by the EPA Regional Administrator. Likewise, if the initial modeling of a source area demonstrates that air quality DVs at all receptors in the analysis are less than or equal to 50 percent of the 1-hour SO<sub>2</sub> NAAQS, and such demonstration is approved by the EPA Regional Administrator, the area would not be subject to ongoing data requirements as well. The EPA believes that including this type of provision in the final rule structures the rule in a balanced way for both modeled and monitored areas in order to meet the objectives of ensuring that such areas continue to meet the standard and continue to protect public health, while recognizing the resource constraints of air agencies.

h. Procedural Approach for Post-Attainment Annual Reporting

i. Summary of Proposal

The EPA proposed two options regarding the procedures by which air agencies would submit ongoing data reports to the EPA for source areas characterized through modeling, and by which the EPA would review and act on them. Under Option 1, the EPA proposed that the air agency would submit a report to the EPA annually as an appendix to its annual monitoring plan. The annual monitoring plan is required to be submitted to the EPA Regional Administrator by July 1 each year. The inclusion of this report as an appendix to the annual monitoring plan would ensure that the report would be subject to the same opportunities for public review and comment that are to be provided for the monitoring plan pursuant to regulations at 40 CFR 58.10. Those regulations specify that if the air agency modifies the monitoring plan from the previous year, then prior to taking final action to approve or disapprove the plan, the EPA would be required to provide an opportunity for public review and comment on the modified plan. The regulations also indicate that if the air agency has already provided a public comment opportunity in developing its revised monitoring plan and has made no further changes to the plan after reviewing the public comments that were received, then it could submit the public comments along with the revised plan to the EPA, and the EPA Regional Administrator would not need to provide a separate opportunity for comment before approving or disapproving the plan.

Under Option 2, the ongoing report would not be submitted to the EPA as an appendix to the annual monitoring network plan, but it would take the form of a separate, independent submittal from the state to the EPA Regional Administrator. The EPA proposed that this report would be due by the same July 1st date each year and that this independent submittal would follow the general guidelines set forth in 40 CFR 58.10 regarding opportunities for public review as described in Option 1, but the report would only include the annual assessments associated with sources in areas that were designated unclassifiable/attainment based on modeling of actual emissions.

In the proposed rule, the EPA requested comment on the two procedural options as well as any alternative ideas suggested by commenters. For any such recommendations, the EPA requested

that the commenter provide a detailed rationale and estimate of any associated costs. See 79 FR 27467, May 13, 2014.

#### ii. Brief Summary of Comments

Some state, tribal and industry commenters recommended that this information be included as an appendix to the annual monitoring plan, rather than as a stand-alone document. One commenter stated that, since both options have a deadline of July 1st each year, a separate document would only add more time and resource use. Several state commenters recommended that the assessment be submitted separately from the annual monitoring plan. These commenters provided the following rationale: Since these documents are not related, they should be kept separate; since the annual report refers to modeling, it will cause less confusion for the general public if it is a separate document from the annual monitoring plan; and because the annual monitoring plan and the emissions inventory submittals are performed by separate work units on different timelines, it would be better to deliver the products separately rather than delay one or the other to deliver them together.

#### iii. EPA Response

After considering the comments received related to both of the proposed options, the EPA believes that the best approach for the final rule is to allow the affected air agencies the discretion to either include the required annual data requirements report for modeled areas either as an appendix to the state's monitoring plan, or as a stand-alone document. The air agency will have the flexibility under the final rule to select the approach that best meets the Agency's workload, schedule, and particular needs. The EPA believes that either of the procedural approaches will be sufficient to implement the ongoing data requirements. Regardless of which approach is chosen by the air agency, the report must be submitted to the respective EPA Regional Office by July 1st annually and made available for public review and comment. The first report is due on July 1st of the year after the effective date of the area's initial designation and additional reports are due July 1st of each subsequent year.

#### E. Other Key Issues and Comments

Comments on the proposed rule also raised several other issues not already addressed in this document. This section identifies and addresses the key issues raised by those comments.

#### 1. March 2015 Consent Decree

The proposed rule did not contain any regulatory deadlines for the EPA to complete area designations under the 2010 SO<sub>2</sub> NAAQS. However, at the same time that the EPA was developing the proposed rule and the final rule, the agency was also engaged in district court litigation from public interest groups and some states and state agencies seeking to have the EPA placed on a binding schedule to complete the designations. The parties in these cases filed complete briefs in one of these cases, resulting first in the court finding that the EPA was liable for having failed to meet the statutory deadline to complete all area designations. Subsequently, the EPA and the other parties conducted extensive settlement discussions over the remedy, *i.e.*, the schedule by which the EPA would complete its duties. This resulted in a settlement between the EPA and the public interest group plaintiffs, which the plaintiff-intervenors did not join.

On June 2, 2014, the EPA published notice of a proposed consent decree reflecting this settlement (*Sierra Club et al v. McCarthy*, Civil Action No. 3:13-cv-3953-SI (N.D. Cal.)). 79 FR 31325. This proposed consent decree included deadlines for the EPA to complete designations in three phases, the latter two of which were due on the same dates that the EPA discussed as its intended designations dates in the preamble to the proposed DRR. The EPA received several comments on the notice informing the public of the proposed consent decree itself, and in response to this proposed rule.

The EPA is not promulgating deadlines for its completion of area designations in this final rule. Therefore, any comments directed to the merits of the consent decree itself are outside the scope of this rulemaking, and we will not respond to them here. Instead, as discussed earlier in this document, on March 2, 2015, the court issued an order entering the consent decree and establishing its deadlines as binding on the EPA. As also explained earlier, the 2017 and 2020 deadlines for the latter two stages of designations established by the consent decree will allow the EPA and states to use the new data and information that is timely generated by the implementation of this rule to inform the designations required to be completed by those dates, but it is not likely that full implementation of the rule can occur quickly enough to support the next round of designations required by the court's order to be completed by July 2, 2016.

#### 2. Recommendations for the EPA To Designate Areas as Unclassifiable

Several commenters recommended that the EPA take prompt action to designate areas with inadequate data for air quality characterization as unclassifiable. A number of commenters asserted that the EPA cannot use the rule to supersede the statutory schedule under which the EPA is required to make area designations, including statutorily-appropriate "unclassifiable" designations. One industry group commented that the CAA does not authorize the EPA to conduct designations according to the schedule anticipated by the proposed rule preamble, commenting that the EPA must instead complete designations in accordance with the schedule under CAA section 107(d)(1) (designating areas unclassifiable where appropriate), and then redesignating unclassifiable areas as either attainment or nonattainment later. Similarly, a state commenter expressed the view that further data are not necessary to meet the CAA. Several commenters also stated that the proposed rule effectively nullifies the "unclassifiable" designation, use of which would have allowed the EPA to meet its statutory deadline. One commenter also stated that the EPA should continue to use the "unclassifiable" designation where appropriate, and should not seek to designate all areas as attainment or nonattainment.

Several commenters also addressed the interrelationship between the proposed rule and the proposed consent decree for settling the lawsuit regarding the EPA's failure to promulgate designations for areas without monitored violations. One state commenter urged that the EPA codify the proposed consent decree into the rule. Another state commenter objected to this suggestion, stating that the proposed consent decree specifies a designations schedule that conflicts with the proposed schedule and compromises a commenter's ability to comment on the impact of that consent decree on the rule. An industrial commenter found the consent decree to undermine the proposed rule. These commenters urged that the EPA re-propose the relationship between the consent decree and the rule. An industry group stated that the issuance of the proposed consent decree undermines the rule because it would require an early round of designations that would be based on modeling, in contravention of the process under the proposed rule that offers the option of basing designations on monitoring data.

As stated previously, the EPA is not establishing or modifying any area designation requirements provided for in section 107 of the CAA through this rulemaking. The purpose of this rulemaking is to require states to characterize air quality in priority areas throughout the country where existing ambient monitors may not be adequately characterizing peak 1-hour SO<sub>2</sub> concentrations. The air quality data obtained as a result of this rulemaking then may be used in future designations or redesignations, as appropriate. While the notice of proposed rulemaking described the EPA's anticipated designations schedule, for purposes of explaining the timeline by which the EPA anticipates that the data the EPA was proposing to require will be used, the timeline for possible future use of these data does not dictate the schedule or the substantive features of the requirements for obtaining data for air quality characterization purposes, and the Agency believes it will be highly valuable to obtain these data even if that occurs after initial designations occur.

While the notice of proposed rulemaking described the EPA's expectations that designations for areas not already completed in August 2013 would be completed either in 2017 or in 2020, the timetables for obtaining additional data are as prompt as the EPA considers reasonable whether or not such data can be used to inform the remaining designations, and thus alternate approaches and timetables for designations would not result in a different timetable for implementation of the rule's requirements. In particular, whether designations proceed according to the approach described in the EPA's notice of proposed rulemaking, or whether areas are first designated unclassifiable and subsequently redesignated to attainment or nonattainment, the same timetable, and substance of requirements for data to support more properly informed future judgments regarding areas' attainment status is warranted. Because this rulemaking is not intended to define the designations process and did not propose regulatory deadlines for issuing designations, it would be inappropriate in this final rulemaking to codify any particular schedule for designations action.

The proposed consent decree referenced by the comments concerns separate legal proceedings that are addressing the EPA's obligations to designate areas under CAA section 107. The commenters have not identified why any potential outcome of those proceedings warrants any particular revision to the rule, nor have they

explained why the validity of the DRR is contingent on use of any particular designations approach. While the court's decision establishing timing requirements for the EPA's designations obligations will of course affect the EPA's approach to designations, including affecting the extent to which the EPA will be able to use the data required under the rule at various times in the designations or redesignations processes, these effects do not determine the validity of the data collection requirements of the rule. For these reasons, the EPA believes that the ability of commenters to address issues relevant to the rule was not compromised by the proposed consent decree and other actions or statements in the proceedings regarding the EPA's timetable for designations, and the EPA finds that re-proposal of the rule is not justified.

### 3. The Cost of Monitoring or Modeling Under this Rule

Several state and industry commenters stated that, because of funding limitations at the state level, any monitoring or modeling done to meet the requirements of the rule would likely need to be done by the affected sources. Commenters also stated that the rule will present yet another burden on the regulated community when facilities are already spending resources on emissions reductions projects that are required as the result of other EPA air quality rules.

Commenters also stated that even if sources voluntarily set up and operate their own monitors, state and local agencies will nevertheless still need to dedicate resources to administer the program, provide technical assistance, conduct performance audits, ensure data quality and submit the data to the EPA's AQS database each year. Commenters also stated that the initial state funding should be provided by the EPA through CAA section 103 or 105 grant funds in order to establish the monitoring sites required to meet the requirements of the rule.

The EPA recognizes that there will be costs and resources required to satisfy the requirements of this rulemaking. As suggested by both state and industry stakeholders who attended the EPA's May–June 2012 stakeholder meetings, in the absence of increased grant funding it may be necessary for air agencies to rebalance their existing grant funds for this purpose, or to consider alternative funding approaches such as working closely with affected sources to assist in funding either the modeling or monitoring required to meet the requirements of the rule. Early planning

may be helpful to address these funding needs.

Because the CAA assigns to states much of the responsibility for developing air quality characterization data, the EPA describes the requirements of this rule in a consistent manner: Air agencies are the entities with principal responsibility to establish and operate monitors, and conduct modeling, and to provide air quality data to the EPA. However, the EPA recognizes that other parties (such as facility owners) also may perform significant portions of the work that this rule requires. The EPA would consider monitoring or modeling conducted by a third party to be an appropriate means for air agencies to obtain the data necessary to meet the requirements of this rule, provided that the state provides oversight to assure that (1) any monitoring is conducted in a manner that is equivalent to SLAMs and quality-assured in accordance with applicable requirements, and (2) any modeling analysis that the state submits, even if it was initially provided to the state by a third party, is done in a reasonable manner and follows the recommendations in the Modeling TAD or as otherwise agree upon with the EPA Regional Office on a case-by-case basis.

### 4. How the DRR Addresses SO<sub>2</sub> Sources in Areas That Are Already Designated

The intent of this DRR is to direct state and tribal air agencies to characterize air quality in areas around the largest sources of SO<sub>2</sub> emissions, through the use of either air quality modeling or ambient monitoring, and to provide such data to the EPA. The additional information required by this rule will be able to inform future action by the EPA or the state (e.g., future designation decisions).

The proposed rule did not specifically address whether the requirement to characterize a sources' SO<sub>2</sub> emission impacts would apply differently based on whether areas containing sources were still undesignated, or whether they had already been designated as nonattainment, attainment, or unclassifiable. However, much of the discussion in the proposed rule preamble concerned how implementation of the rule might inform future area designations, thus implying that the air quality characterization requirement might apply only to areas that remained undesignated at the time of the rule's implementation. The EPA believes it is necessary to clarify how the rule applies to areas that have already been designated in some manner, either during the initial round of designations in August 2013 or in

subsequent rounds of designations pursuant to the March 2015 consent decree.

The first question is whether air agencies are required under this rule to characterize air quality near sources in areas that were designated as nonattainment in August 2013. *See* 78 FR 47191, August 5, 2013. In general, we expect nonattainment plans to provide adequate characterization of the impacts of sources within those nonattainment areas. Therefore, we have concluded that an air agency will not be required under this rule to characterize air quality around SO<sub>2</sub> sources located in a designated nonattainment area. Specifically, we have clarified the definition of “applicable source” in § 51.1200 of the final rule to be “a stationary source that is (1) not located in a designated nonattainment area, and (2) has annual actual SO<sub>2</sub> emissions of 2,000 tons or more, or has been identified by an air agency or by the EPA Regional Administrator as requiring further air quality characterization.” Thus, as a general matter, this rule does not require the state’s January 2016 list of sources triggering the requirements of this rule to include sources located within areas already designated as nonattainment.

However, it may be possible that in some cases an SO<sub>2</sub> source or group of sources within the boundary of an existing nonattainment area can have significant impacts outside the nonattainment area, potentially raising concerns that these impacts might not be adequately evaluated in a nonattainment plan. The EPA notes that for such cases, the air agency and the EPA Regional Administrator retain the authority under this rule to require additional characterization of air quality around specific sources located in an existing nonattainment area, in the same manner that they retain the authority, as warranted, to require characterization of air quality around sources that are below the emissions threshold identified in this rule.

Related questions also arise for sources in areas that will be subject to evaluation and designation by July 2016 under the March 2015 consent decree regarding SO<sub>2</sub> designations. Because all sources that meet the March 2015 consent decree criteria for designation by July 2016 will also exceed the 2,000 ton threshold under this DRR, these sources will need to be included on the January 2016 list of sources subject to requirements for air quality characterization under this rule. Subsequent designations do not alter this list. The list is a permanent list of prioritized sources that excludes

sources in areas designated as nonattainment before January 2016 and is not altered by designations promulgated after January 2016. In particular, the list of sources would not be altered by promulgation of nonattainment designations in July 2016. Nevertheless, the EPA expects that if the area around a “consent decree” source is designated as nonattainment by July 2016, pursuant to the consent decree, then the information that was adequate to inform this designation would also satisfy the air agency’s obligation under this rule to submit modeling information in January 2017 characterizing air quality around that source.

The next question is how this rule applies to sources in areas that have been designated as “unclassifiable” or as “unclassifiable/attainment.”<sup>12</sup> The EPA did not apply these designations to any areas in August 2013, but the EPA may apply these designations to some areas in the designations required to be completed by July 2016. This rule requires air quality characterization for areas previously designated as unclassifiable, just as it requires air quality characterization for undesignated areas. If the EPA has previously determined through a designation action that sufficient information has not yet been identified to support an attainment or nonattainment designation (*i.e.*, the area was initially designated as unclassifiable), then the additional information required by this rule will be used to inform possible future actions by the EPA or the state (*e.g.*, to determine whether the area is attaining or not attaining the standard, and change designation status).

With regard to “unclassifiable/attainment” areas, no areas were given this designation in the August 2013 designations. However, it is possible that some areas may be given this designation in the July 2016 designations based on relevant air quality characterization information (such as air quality modeling) that has been provided by the air agency or other

parties in the designations process. The applicable sources in any such areas designated pursuant to the March 2015 consent decree would have also been included in the list of sources that air agencies would be required to submit to the EPA in January 2016 according to this rule. If an area has already been designated by the EPA as “unclassifiable/attainment” by July 2016 pursuant to the consent decree, then the EPA expects that, as was the case for areas as designated nonattainment, the information that was adequate to inform an unclassifiable/attainment designation would also satisfy the air agency’s obligation under this rule to submit modeling information in January 2017 characterizing air quality around that source. As a result, under this rule, the air agency would not be required to provide additional air quality characterization information to the EPA by January 2017.

However, these already-designated “unclassifiable/attainment” areas would nevertheless be subject to the ongoing data requirements included in § 51.1205 of this rule. While modeling for purposes of informing designations promulgated by July 2016 would also be considered modeling to address the requirements of this rule, the EPA is promulgating revised rule language that clarifies that the ongoing data requirements apply to areas modeled based on actual emissions whether that modeling was conducted for purposes of informing designations by July 2016 or conducted only for satisfying the requirements of this rule. Accordingly, § 51.1205(b) has been modified to apply to any attainment area designated based on modeling of actual emissions to characterize air quality.

##### 5. How Air Agencies Should Address Modeling and Monitoring in Multi-State Areas To Meet the Requirements of the Rule

As with the previous issue, a review of the comments and questions received from states has made the EPA aware of the need to clarify how the rule applies to situations where an applicable source that is located in one state or tribal jurisdiction has an impact on SO<sub>2</sub> concentrations in one or more other jurisdictions. While the final rule preserves the option of the air agency of the jurisdiction in which the source is located to choose how to satisfy the air quality characterization requirements of the rule (*i.e.*, through either monitoring or modeling), the EPA urges all air agencies involved to consult and coordinate in order to make appropriate decisions concerning whether modeling

<sup>12</sup> While states have and may continue to submit designations recommendations identifying areas as “attainment,” the EPA expects to continue its traditional approach, where appropriate, of using a designation category of “unclassifiable/attainment” for areas that the EPA determines meet the NAAQS. The EPA expects to reserve the category “unclassifiable” for areas where the EPA cannot determine based on available information whether the area is meeting or not meeting the NAAQS or where the EPA cannot determine whether the area contributes to a violation in a nearby area. *See* SO<sub>2</sub> designations guidance issued by Stephen D. Page on March 20, 2015, available at <http://www.epa.gov/airquality/sulfurdioxide/pdfs/20150320SO2designations.pdf>.

or monitoring would be the most effective method to characterize the peak 1-hour SO<sub>2</sub> concentrations in the ambient air affected by such sources.

If the jurisdiction in which the source is located prefers to employ ambient monitoring to characterize air quality, the EPA believes it would be appropriate to use ambient monitoring only if: (1) The air agency coordinates with the other jurisdiction in identifying appropriate ambient monitoring sites; and (2) there is an agreement established with the other jurisdiction (in which peak 1-hour SO<sub>2</sub> impacts are being experienced), and possibly with the facility owner, regarding logistical, financial and operational responsibilities associated with the purchase, installation and operation of the monitor or monitors that is acceptable to all parties. However, if one or both jurisdictions do not wish to employ ambient monitoring, and a monitoring agreement cannot be reached, the EPA believes that the obligation to characterize air quality rests with the jurisdiction in which the source is located. Without an adequate multi-jurisdiction monitoring plan, the air agency would need to use modeling analyses to characterize air quality in the multi-jurisdiction area. Consultation among all involved jurisdictions will be important for planning and conducting technically appropriate modeling. The EPA expects that early and active coordination among all involved parties can lead to beneficial agreements for characterizing air quality in multi-jurisdiction areas, and the EPA will work with air agencies to help facilitate such agreements.

#### V. Environmental Justice Considerations

The EPA believes the human health or environmental risk addressed by this action will not have disproportionately high and adverse human health or environmental effects on minority, low-income, or indigenous populations because it does not affect the level of protection provided to human health or the environment under the SO<sub>2</sub> NAAQS. When promulgated, these regulations will require that air agencies characterize air quality around certain large emissions sources, or secure emission limits on sources to reduce annual emissions below 2,000 tpy. It is intended that the actions resulting from this rule would lead to greater protection for U.S. citizens, including minority, low-income, or indigenous populations, by reducing exposure to high ambient concentrations of SO<sub>2</sub>. In addition, this rule will help communities by informing residents

about ambient air quality around the largest sources of SO<sub>2</sub>.

#### VI. Statutory and Executive Order Reviews

##### A. Executive Order 12866: Regulatory Planning and Review and Executive Order 13563: Improving Regulation and Regulatory Review

This action is not an economically significant action, but raises novel policy issues and was submitted to the Office of Management and Budget (OMB) for review. Any changes made in response to OMB recommendations have been documented in the docket.

##### B. Paperwork Reduction Act (PRA)

The information collection activities in this rule have been submitted for approval to the Office of Management and Budget (OMB) under the PRA. The Information Collection Request (ICR) document that the EPA prepared has been assigned EPA ICR number 2495.01. A copy of the ICR is available in the docket for this rule, and is briefly summarized here. The information collection requirements are not enforceable until OMB approves them.

The EPA is requiring air agencies to more extensively characterize ambient SO<sub>2</sub> air quality concentrations, pursuant to sections 110(a)(2)(B), 110(a)(2)(K), 301(a) and 114 of the CAA. For purposes of analysis of the estimated paperwork burden, the EPA assumed that 43 states and tribes would take actions to characterize air quality through either air quality modeling or ambient monitoring in 412 areas around SO<sub>2</sub> sources emitting 2,000 tpy or more across the country, and such states would submit the results of these analyses to the EPA. Under this rule, the air agency will have the ability to choose, on an area-by-area basis, the analytical approach to follow for characterizing air quality around each qualifying source. For this reason, there is no way of determining exactly how many areas may be characterized through ambient monitoring versus air quality modeling approaches. Therefore, this section presents two sets of estimated costs, one that assumes all source areas would be characterized through ambient monitoring, and the other that assumes that all source areas would be characterized through air quality modeling.

Potential ambient air monitoring costs are estimated based on the assumption that air quality for each of the 412 SO<sub>2</sub> sources exceeding the 2,000 tpy threshold would be characterized through a single newly deployed air monitor. (Note, however, that the

Monitoring TAD discusses situations where more than one monitor may be appropriate or necessary to properly characterize peak 1-hour SO<sub>2</sub> concentrations in certain areas, which would increase costs proportionally.) Estimates are provided for a 3-year period and include a calculation for equipment amortization over 7 years (as is typically done in monitoring-related ICRs). For the period of 2016, 2017, and 2018 (monitoring related expenditures would begin in 2016), the total approximate average annual monitoring cost, including a calculation for equipment amortization, is \$8,662,110 (total capital, and labor and non-labor operation and maintenance) with a total burden of 102,869 hours. The annual labor costs associated with these hours is \$7,080,572. Included in the \$8,662,110 total are other annual costs of non-labor operations and maintenance of \$706,827 and equipment and contract costs of \$874,711. For reference purposes, an estimate for initial establishment of a new SO<sub>2</sub> monitoring station is \$92,614 (does not include equipment amortization). In addition to the costs that would be incurred by the state and local air agencies, there would be an estimated burden to the EPA related to salary cost and equipment cost, etc., of a total of 52,717 hours and \$776,005.

Potential air quality modeling costs are estimated based on the assumption that air quality for each of the 412 SO<sub>2</sub> sources exceeding the 2,000 tpy threshold would be characterized through air quality modeling analyses. Based on market research, stakeholder feedback and assumptions about the procedures to follow when conducting modeling for designations purposes,<sup>13</sup> an estimate of modeling costs for a single modeling run centered on an identified source would be approximately \$30,000. If air agencies choose to characterize air quality through modeling analyses around all 412 sources expected to be identified as exceeding the source threshold, then total national costs for modeling analyses would be estimated at \$12,360,000. If these costs were incurred over the course of 3 years, then the approximate annual cost for each year over that period would be \$4,120,000.

An agency may not conduct or sponsor, and a person is not required to respond to, a collection of information unless it displays a currently valid OMB

<sup>13</sup> The Draft SO<sub>2</sub> NAAQS Designations Modeling Technical Assistance Document can be found at: <http://www.epa.gov/airquality/sulfurdioxide/pdfs/SO2ModelingTAD.pdf>.

control number. The OMB control numbers for the EPA's regulations in 40 CFR are listed in 40 CFR part 9. When OMB approves this ICR, the agency will announce that approval in the **Federal Register** and publish a technical amendment to 40 CFR part 9 to display the OMB control number for the approved information collection activities contained in this final rule.

#### *C. Regulatory Flexibility Act (RFA)*

I certify that this action will not have a significant economic impact on a substantial number of small entities under the RFA. In making this determination, the impact of concern is any significant adverse economic impact on small entities. An agency may certify that a rule will not have a significant economic impact on a substantial number of small entities if a rule relieves regulatory burden, has no net burden or otherwise has a positive economic effect on the small entities subject to the rule. This final rule will not impose any requirements directly on small entities. Entities potentially affected directly by this final rule include state, local and tribal governments and none of these governments are small entities. Other types of small entities are also not directly subject to the requirements of this rule.

#### *D. Unfunded Mandates Reform Act (UMRA)*

This action does not contain any unfunded mandate of \$100 million or more as described in UMRA, 2 U.S.C. 1531, and does not significantly or uniquely affect small governments.

#### *E. Executive Order 13132: Federalism*

This action does not have federalism implications. It will not have substantial direct effects on the states, on the relationship between the national government and the states, or on the distribution of power and responsibilities among the various levels of government. The requirement to characterize air quality to inform the area designation process for the revised NAAQS is imposed by the CAA. This rule is intended to interpret those requirements as they apply to the 2010 1 hour SO<sub>2</sub> NAAQS.

#### *F. Executive Order 13175: Consultation and Coordination With Indian Tribal Governments*

This action does not have tribal implications, as specified in Executive Order 13175. It would not have a substantial direct effect on one or more Indian tribes. Furthermore, this regulation does not affect the

relationship or distribution of power and responsibilities between the federal government and Indian tribes. The CAA and the Tribal Air Rule establish the relationship of the federal government and tribes in characterizing air quality and developing plans to attain the NAAQS, and this regulation does nothing to modify that relationship. Thus, Executive Order 13175 does not apply to this action.

Consistent with the EPA Policy on Consultation and Coordination with Indian tribes, the EPA held several meetings with tribal environmental professionals to discuss issues associated with this rule, including discussions at the National Tribal Forum on May 1, 2013, and on National Tribal Air Association policy calls. These meetings discussed the SO<sub>2</sub> implementation White Paper. The EPA provided an opportunity for tribes and stakeholders to provide written comments on the concepts discussed in the White Paper. Summaries of these meetings are included in the docket for this rule. The EPA also provided information on the proposed rule and conducted consultation with the National Tribal Air Association in the form of a briefing on April 24, 2014, and a webinar on May 21, 2014.

#### *G. Executive Order 13045: Protection of Children From Environmental Health and Safety Risks*

The EPA interprets Executive Order 13045 as applying only to those regulatory actions that concern environmental health or safety risks that the EPA has reason to believe may disproportionately affect children, per the definition of "covered regulatory action" in section 2-202 of the Executive Order. This action is not subject to Executive Order 13045 because it does not directly involve an environmental health risk or safety risk.

#### *H. Executive Order 13211: Actions Concerning Regulations That Significantly Affect Energy Supply, Distribution, or Use*

This action is not a "significant energy action" because it is not likely to have a significant adverse effect on the supply, distribution or use of energy. The EPA is finalizing this SO<sub>2</sub> DRR to require air agencies to more extensively characterize ambient SO<sub>2</sub> air quality concentrations, pursuant to sections 110(a)(2)(B), 110(a)(2)(K), 301(a) and 114 of the CAA. The rule does not prescribe specific control strategies by which the SO<sub>2</sub> NAAQS will be met. Such strategies will be developed by states on a case-by-case basis only if the information generated by this rule

results in an area being designated nonattainment, thereby triggering the need for the state to develop an attainment plan for the area. The EPA cannot predict whether the attainment plan prepared by the state will include regulations on energy suppliers, distributors, or users. Thus, the EPA concludes that this rule is not likely to have any adverse energy effects.

#### *I. National Technology Transfer and Advancement Act*

This action does not involve technical standards.

#### *J. Executive Order 12898: Federal Actions To Address Environmental Justice in Minority Populations and Low-Income Populations*

The EPA believes the human health or environmental risk addressed by this action will not have potential disproportionately high and adverse human health or environmental effects on any population, including any minority, low-income or indigenous populations, because it does not affect the level of protection provided to human health or the environment. That level of protection is established by the NAAQS itself. The results of the evaluation of environmental justice considerations is contained in section V of this preamble titled, "Environmental Justice Considerations."

#### *K. Congressional Review Act (CRA)*

This action is subject to the CRA, and the EPA will submit a rule report to each House of the Congress and to the Comptroller General of the United States. This action is not a "major rule" as defined by 5 U.S.C. 804(2).

#### *L. Judicial Review*

Under section 307(b)(1) of the CAA, petitions for judicial review of this final action must be filed in the United States Court of Appeals for the District of Columbia Circuit by October 20, 2015. Filing a petition for reconsideration by the Administrator of this final action does not affect the finality of this action for the purposes of judicial review nor does it extend the time within which a petition for judicial review must be filed, and shall not postpone the effectiveness of this action.

#### **Statutory Authority**

The statutory authority for this action is provided by 42 U.S.C. 7401 *et seq.*, and particularly sections 7403, 7407, 7410, 7414 and 7601.

**List of Subjects in 40 CFR Part 51**

Environmental protection, Air pollution control, Intergovernmental relations, Sulfur oxides.

Dated: August 10, 2015.

**Gina McCarthy,**  
Administrator.

For the reasons stated in the preamble, title 40, chapter I, part 51 of the Code of Federal Regulations is amended as follows:

**PART 51—REQUIREMENTS FOR PREPARATION, ADOPTION, AND SUBMITTAL OF IMPLEMENTATION PLANS**

- 1. The authority citation for part 51 continues to read as follows:

**Authority:** 23 U.S.C. 101; 42 U.S.C. 7401–7671q.

- 2. Subpart BB is added to read as follows:

**Subpart BB—Data Requirements for Characterizing Air Quality for the Primary SO<sub>2</sub> NAAQS**

Sec.

- 51.1200 Definitions.  
51.1201 Purpose.  
51.1202 Applicability.  
51.1203 Air agency requirements.  
51.1204 Enforceable emission limits providing for attainment.  
51.1205 Ongoing data requirements.

**Subpart BB—Data Requirements for Characterizing Air Quality for the Primary SO<sub>2</sub> NAAQS**

**§ 51.1200 Definitions.**

The following definitions apply for the purposes of this subpart. All terms not defined herein will have the meaning given them in § 51.100 or in the Clean Air Act (CAA). *Air agency* means the agency or organization responsible for air quality management within a state, local governmental jurisdiction, territory or area subject to tribal government. *Annual SO<sub>2</sub> emissions data* means the quality-assured annual SO<sub>2</sub> emissions data for a stationary source. Such data may have been required to be reported to the EPA in accordance with an existing regulatory requirement (such as the Air Emissions Reporting Rule or the Acid Rain Program); however, annual SO<sub>2</sub> emissions data may be obtained or determined through other reliable means as well.

*Applicable source* means a stationary source that is:

- (1) Not located in a designated nonattainment area, and
- (2) Has actual annual SO<sub>2</sub> emissions data of 2,000 tons or more, or has been identified by an air agency or by the

EPA Regional Administrator as requiring further air quality characterization. *2010 SO<sub>2</sub> NAAQS* means the primary National Ambient Air Quality Standard for sulfur oxides (sulfur dioxide) as codified at 40 CFR 50.17, as effective August 23, 2010.

**§ 51.1201 Purpose.**

The purpose of this subpart is to require air agencies to develop and submit air quality data characterizing maximum 1-hour ambient concentrations of SO<sub>2</sub> across the United States through either ambient air quality monitoring or air quality modeling analysis at the air agency's election. These monitoring and modeling data may be used in future determinations by the EPA regarding areas' SO<sub>2</sub> NAAQS attainment status, or for other actions designed to ensure attainment of the 2010 SO<sub>2</sub> NAAQS and provide protection to the public from the short-term health effects associated with exposure to SO<sub>2</sub> concentrations that exceed the NAAQS.

**§ 51.1202 Applicability.**

This subpart applies to any air agency in whose jurisdiction is located one or more applicable sources of SO<sub>2</sub> emissions that have annual actual SO<sub>2</sub> emissions of 2,000 tons or more; or in whose jurisdiction is located one or more sources of SO<sub>2</sub> emissions that have been identified by the air agency or by the EPA Regional Administrator as requiring further air quality characterization. For the purposes of this subpart, the subject air agency shall identify applicable sources of SO<sub>2</sub> based on the most recently available annual SO<sub>2</sub> emissions data for such sources.

**§ 51.1203 Air agency requirements.**

(a) The air agency shall submit a list of applicable SO<sub>2</sub> sources identified pursuant to § 51.1202 located in its jurisdiction to the EPA by January 15, 2016. This list may be revised by the Regional Administrator after review based on available SO<sub>2</sub> emissions data.

(b) For each source area subject to requirements for air quality characterization, the air agency shall notify the EPA by July 1, 2016, whether it has chosen to characterize peak 1-hour SO<sub>2</sub> concentrations in such area through ambient air quality monitoring; characterize peak 1-hour SO<sub>2</sub> concentrations in such area through air quality modeling techniques; or provide federally enforceable emission limitations by January 13, 2017 that limit emissions of applicable sources to less than 2,000 tpy, in accordance with paragraph (e) of this section, or provide documentation that the applicable

source has permanently shut down. Emission limits in accordance with paragraph (e) of this section may be established in lieu of conducting monitoring or modeling unless, in the judgment of the air agency or the EPA Regional Administrator, the area warrants further air quality characterization even with the establishment of any new emission limit(s). If the air agency has chosen to establish requirements to limit emissions for applicable sources in an area, the notification from the air agency shall describe the requirements and emission limits the air agency intends to apply. For any area with multiple applicable sources, the air agency (or air agencies if a multi-state area) shall use the same technique (monitoring, modeling, or emissions limitation) for all applicable sources in the area. If multiple air agencies have applicable sources in an area, the air agencies must consult with each other to employ a common technique for the area.

(c) *Monitoring.* For each area identified in the notification submitted pursuant to paragraph (b) of this section as an area for which SO<sub>2</sub> concentrations will be characterized through ambient monitoring, the required monitors shall be sited and operated either as SLAMS or in a manner equivalent to SLAMS. In either case, monitors shall meet applicable criteria in 40 CFR part 58, appendices A, C, and E and their data shall be subject to data certification and reporting requirements as prescribed in 40 CFR 58.15 and 58.16. These requirements include quarterly reporting of monitoring data to the Air Quality System, and the annual certification of data by May 1 of the following year.

(1) The air agency shall include relevant information about monitors used to meet the requirements of this paragraph (c) in the air agency's Annual Monitoring Network Plan required by 40 CFR 58.10 due July 1, 2016. The air agency shall consult with the appropriate EPA Regional Office in the development of plans to install, supplement, or maintain an appropriate ambient SO<sub>2</sub> monitoring network pursuant to the requirements of 40 CFR part 58 and of this subpart.

(2) All existing, *new*, or relocated ambient monitors intended to meet the requirements of this paragraph (c) must be operational by January 1, 2017 and must be operated continually until approved for shut down by EPA.

(3) Any SO<sub>2</sub> monitor identified by an air agency in its approved Annual Monitoring Network Plan as having the purpose of meeting the requirements of this paragraph (c) that: Is not located in

an area designated as nonattainment as the 2010 SO<sub>2</sub> NAAQS is not also being used to satisfy other ambient SO<sub>2</sub> minimum monitoring requirements listed in 40 CFR part 58, appendix D, section 4.4; and is not otherwise required as part of a SIP, permit, attainment plan or maintenance plan, may be eligible for shut down upon EPA approval if it produces a design value no greater than 50 percent of the 2010 SO<sub>2</sub> NAAQS from data collected in either its first or second 3-year period of operation. The air agency must receive EPA Regional Administrator approval of a request to cease operation of the monitor as part of the EPA's action on the Annual Monitoring Network Plan under 40 CFR 58.10 prior to shutting down any qualifying monitor under this paragraph (c).

(d) *Modeling.* For each area identified in the notification submitted pursuant to paragraph (b) of this section as an area for which SO<sub>2</sub> concentrations will be characterized through air quality modeling, the air agency shall submit by July 1, 2016, a technical protocol for conducting such modeling to the Regional Administrator for review. The air agency shall consult with the appropriate EPA Regional Office in developing these modeling protocols.

(1) The modeling protocol shall include information about the modeling approach to be followed, including but not limited to the model to be used, modeling domain, receptor grid, emissions dataset, meteorological dataset and how the air agency will account for background SO<sub>2</sub> concentrations.

(2) Modeling analyses shall characterize air quality based on either actual SO<sub>2</sub> emissions from the most recent 3 years, or on any federally enforceable allowable emission limit or limits established by the air agency or the EPA and that are effective and require compliance by January 13, 2017.

(3) Except as provided by § 51.1204, the air agency shall conduct the modeling analysis for any applicable source identified by the air agency pursuant to paragraph (a) of this section, and for its associated area and any nearby area, as applicable, and submit the modeling analysis to the EPA Regional Office by January 13, 2017.

(e) *Federally enforceable requirement to limit SO<sub>2</sub> emissions to under 2,000 tons per year.* For each area identified

in the notification submitted pursuant to paragraph (b) of this section as an area for which the air agency will adopt federally enforceable requirements in lieu of characterizing air quality through monitoring or modeling, the air agency shall submit documentation to the EPA by January 13, 2017, showing that such requirements have been adopted, are in effect, and been made federally enforceable by January 13, 2017, through an appropriate legal mechanism, and the provisions either:

(1) Require the applicable sources in the area to emit less than 2,000 tons of SO<sub>2</sub> per year for calendar year 2017 and thereafter; or

(2) Document that the applicable sources in the area have permanently shut down by January 13, 2017.

#### **§ 51.1204 Enforceable emission limits providing for attainment.**

At any time prior to January 13, 2017, the air agency may submit to the EPA federally enforceable SO<sub>2</sub> emissions limits (effective no later than January 13, 2017) for one or more applicable sources that provide for attainment of the 2010 SO<sub>2</sub> NAAQS in the area affected by such emissions. The submittal shall include associated air quality modeling and other analyses that demonstrate that all modeling receptors in the area will not violate the 2010 SO<sub>2</sub> NAAQS, taking into account the updated allowable emission limits on applicable sources as well as emissions limits that may apply to any other sources in the area. The air agency shall not be subject to the ongoing data requirements of § 51.1205 for such area if the air quality modeling and other analyses demonstrate that the area will not violate the 2010 SO<sub>2</sub> NAAQS.

#### **§ 51.1205 Ongoing data requirements.**

(a) *Monitored areas.* For any area where SO<sub>2</sub> monitoring was conducted to characterize air quality pursuant to § 51.1203, the air agency shall continue to operate the monitor(s) used to meet those requirements and shall continue to report ambient data pursuant to existing ambient monitoring regulations, unless the monitor(s) have been approved for shut down by the EPA Regional Administrator pursuant to § 51.1203(c)(3) or pursuant to 40 CFR 58.14.

(b) *Modeled areas.* For any area where modeling of actual SO<sub>2</sub> emissions serve as the basis for designating such area as

attainment for the 2010 SO<sub>2</sub> NAAQS, the air agency shall submit an annual report to the EPA Regional Administrator by July 1 of each year, either as a stand-alone document made available for public inspection, or as an appendix to its Annual Monitoring Network Plan (also due on July 1 each year under 40 CFR 58.10), that documents the annual SO<sub>2</sub> emissions of each applicable source in each such area and provides an assessment of the cause of any emissions increase from the previous year. The first report for each such area is due by July 1 of the calendar year after the effective date of the area's initial designation.

(1) The air agency shall include in such report a recommendation regarding whether additional modeling is needed to characterize air quality in any area to determine whether the area meets or does not meet the 2010 SO<sub>2</sub> NAAQS. The EPA Regional Administrator will consider the emissions report and air agency recommendation, and may require that the air agency conduct updated air quality modeling for the area and submit it to the EPA within 12 months.

(2) An air agency will no longer be subject to the requirements of this paragraph (b) for a particular area if it provides air quality modeling demonstrating that air quality values at all receptors in the analysis are no greater than 50 percent of the 1-hour SO<sub>2</sub> NAAQS, and such demonstration is approved by the EPA Regional Administrator.

(c) Any air agency that demonstrates that an area would meet the 2010 SO<sub>2</sub> NAAQS with allowable emissions is not required pursuant to paragraph (b) of this section to submit future annual reports for the area.

(d) If modeling or monitoring information required to be submitted by the air agency to the EPA pursuant to this subpart indicates that an area is not attaining the 2010 SO<sub>2</sub> NAAQS, the EPA may take appropriate action, including but not limited to requiring adoption of enforceable emission limits to ensure continued attainment of the 2010 SO<sub>2</sub> NAAQS, designation or redesignation of the area to nonattainment, or issuance of a SIP Call.

Maryland Department of the Environment Response to Comments  
Regarding this 1-Hour SO<sub>2</sub> State Implementation Plan

... page 2182

## Appendix E Public Hearing

### MARYLAND DEPARTMENT OF THE ENVIRONMENT

#### RESPONSE TO COMMENTS

Received in

SUBMISSIONS and at the PUBLIC HEARING

Hearing held on January 16, 2020 in Baltimore, Maryland

In relation to

*State of Maryland 1-Hour Sulfur Dioxide (SO<sub>2</sub>) National Ambient Air Quality Standard (NAAQS)*

*State Implementation Plan for the*

*Anne Arundel County and Baltimore County, MD (“Wagner”) Nonattainment Area*

A public hearing will be held on January 16, 2020, at the Maryland Department of the Environment (MDE) Headquarters, 1800 Washington Boulevard, Baltimore, Maryland 21230.

Additional information on the hearing and comments received, including responses to the comments, will be included in this appendix after the public comment period and hearing are complete.
