University of Maryland  
Solomons, Maryland 20688

## BENTHOS METHODS

Four scientific cruises to Hart and Miller Islands were made aboard the University of Maryland Center for Environmental and Estuarine Studies Research Vessel Aquarius on 23-25 August, and 15-17 November, 1982; 21-23 February, and 16-18 May, 1983.

The stations monitored for the second year of study were in the same locations as the previous year (Fig. 1). The coordinates for these stations along with station designation numbers from the DFR benthic study of 1972-78 are given in Table 1.

At each station three replicate bottom samples were taken with a vanVeen grab which takes a  $.1m^2$  area of the sediments varying from 6 to 15 cm in depth depending on the softness of the bottom. The data print-out identifies these as Grab 1, 2, and 3, and they were washed through a 1.0mm screen. Grab 1, however, was further collected on a .5mm screen to obtain smaller juvenile forms. This is so indicated on the print-out (Tables 2, 3, 4, 5). The samples were preserved in the field with 10% formalin colored with a small amount of rose Bengal to facilitate sorting specimens from detritus.

The number of each species was counted and recorded separately for each of the replicate grabs. Specimens which were damaged and in parts were included in the count only if the head portion could be identified.

Water temperatures and salinities were taken by means of an induction salinometer near the bottom of the water column at selected stations (Tables 6, 7, 8, 9). Depths were recorded from the ship's recording fathometer and stations were located by means of the radar unit and Lorar C.

A small volume of sediment from one of the triplicate samples at each station was removed for sediment grain size analysis (Tables 5, 6, 7). The sample was processed in the laboratory by washing through a No. 230 (62 microns) U.S. Standard Sieve to collect a sample of the silts and clays in the filtrate. The sand fraction which remained on the screen was dried in an oven at approximately 100C and sieved through a nest of sieves No. 35 (500 microns), No. 60 (250 microns), and No. 120 (125 microns). The sample of the filtrate which contained the silts and clays was then filtered through a Millipore GF/C filter and dried to a constant weight. A second aliquot of the filtrate was used for clay analysis after it was allowed to sit undisturbed for exactly two hours. This 5Cml sample was also filtered through a Millipore filter and then allowed to dry in a dessicator before weighing. The percentage of the weights for the various sand's, silts and clay fractions were then determined, based on the weight of the original sample.

Technical Report Series No. 13-84, Center for Environmental  
and Estuarine Studies of the University of Maryland.
