SUBJECT: **AMENDED CONCEPTUAL SITE MODEL UPDATE REPORT**
Inactive Exxon Facility #28077
14258 Jarrettsville Pike, Phoenix, Maryland
Case Number 2006-0303-BA2
Facility I.D. No. 12342

Dear Ms. Bull:

Enclosed please find the Amended Conceptual Site Model Report for the above referenced site. This submittal includes updates to the August 3, 2026 Conceptual Site Model Update Report to address comments from MDE, including:

- Updates to Figure 4 and Figure 16, previously submitted electronically to MDE on September 8, 2026;
- Updates to Appendix I previously submitted electronically to MDE on September 3, 2026;
- Splitting Appendix L into Appendix L1 for monitoring wells and Appendix L2 for private supply wells and addressing updates to Appendix L previously submitted electronically to MDE on September 3, 2026; and
- Updating Appendix F with sample depths for monitoring wells MW-27B, MW-82B, and MW-146B.

Please feel free to contact us at 410.850.0404 if you have questions or require additional information.

Sincerely,

KLEINFELDER

CONCEPTUAL SITE MODEL UPDATE
INACTIVE EXXON FACILITY #28077
14258 JARRETTSVILLE PIKE, PHOENIX, MARYLAND
MDE CASE NO. 2006-0303-BA2
MDE FACILITY I.D. NO. 12342

EXECUTIVE SUMMARY

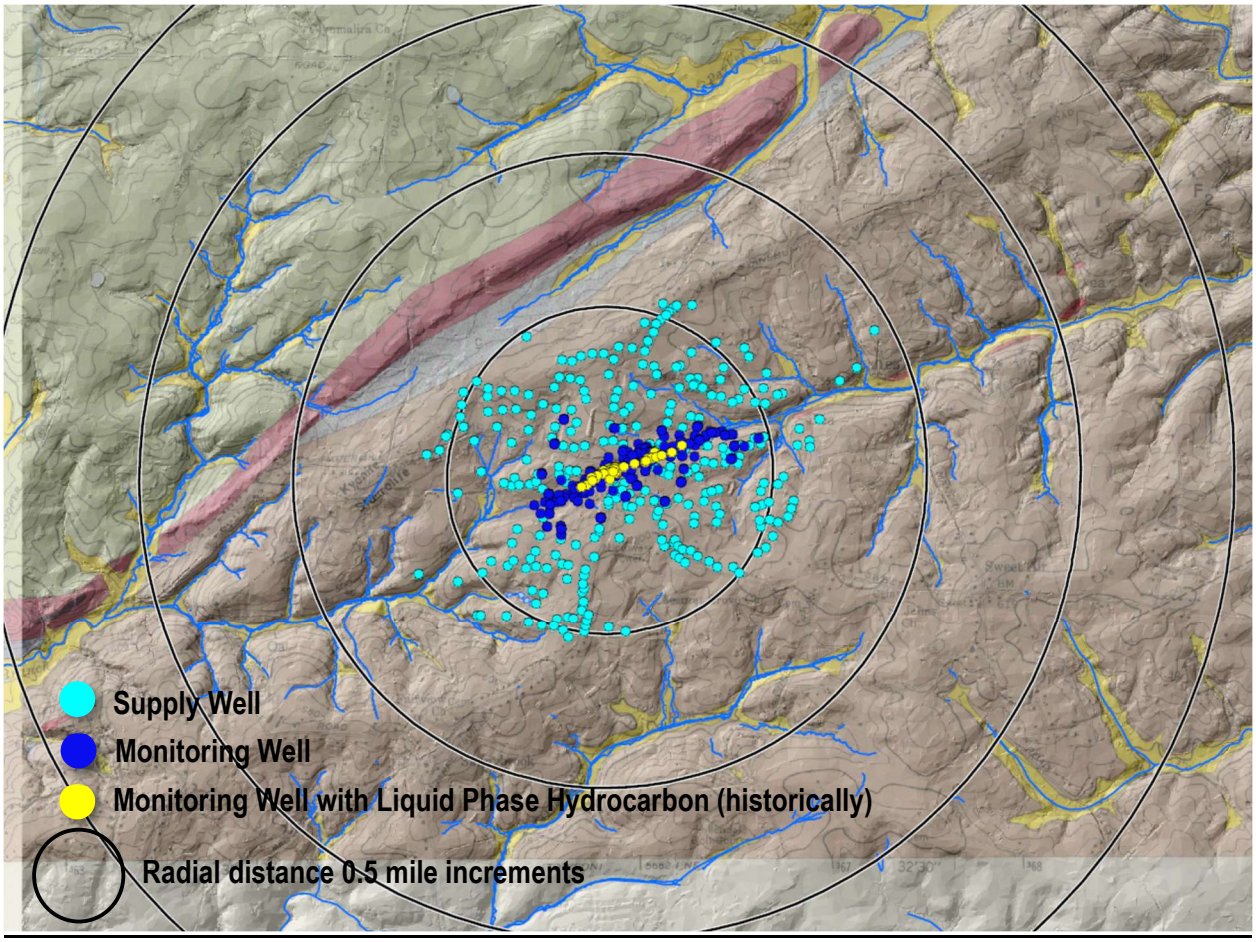
This report is provided to the Maryland Department of the Environment (MDE) Oil Control Program (OCP) by Kleinfelder on behalf of ExxonMobil Environmental Solutions (EMES) for inactive Exxon retail station #28077 (MDE Case Number 2006-0303-BA2) located at 14258 Jarrettsville Pike in Phoenix Maryland.

Extensive site characterization, remediation, and monitoring activities have been conducted by EMES under the direction of the MDE upon detection of a release of unleaded gasoline at the former service station in 2006, representing over 20 years of characterization and monitoring, including approximately 18 years during active remediation, and 2.5 years of post-remediation monitoring. These assessment and remediation activities have been conducted pursuant to an Interim Remedial Measures (IRM) Plan and a Corrective Action Plan (CAP) prepared in accordance with Code of Maryland Regulations (COMAR) 26.10.09 and requested by the MDE. The assessment and remediation activities are also being conducted under a 2008 Consent Decree between the State of Maryland and Exxon Mobil Corporation (Circuit Court for Baltimore County, Maryland, 2008).

A consolidated conceptual site model (CSM) is presented that integrates the chemical, geologic, and hydraulic information obtained from the multiple investigative, monitoring, and remediation activities conducted for the project. The CSM consists of the following elements, which are described in detail in the body of the report:

- Contaminant phases and affected media;
- Source, pathways, and potential receptors;
- Hydrogeologic framework;
- Response to remediation and remedial effectiveness;
- Summary of conditions and groundwater quality;
- Risk summary; and,
- Alternate sources of impacts.

© 2026 Kleinfelder



Key aspects of the CSM are summarized as follows:

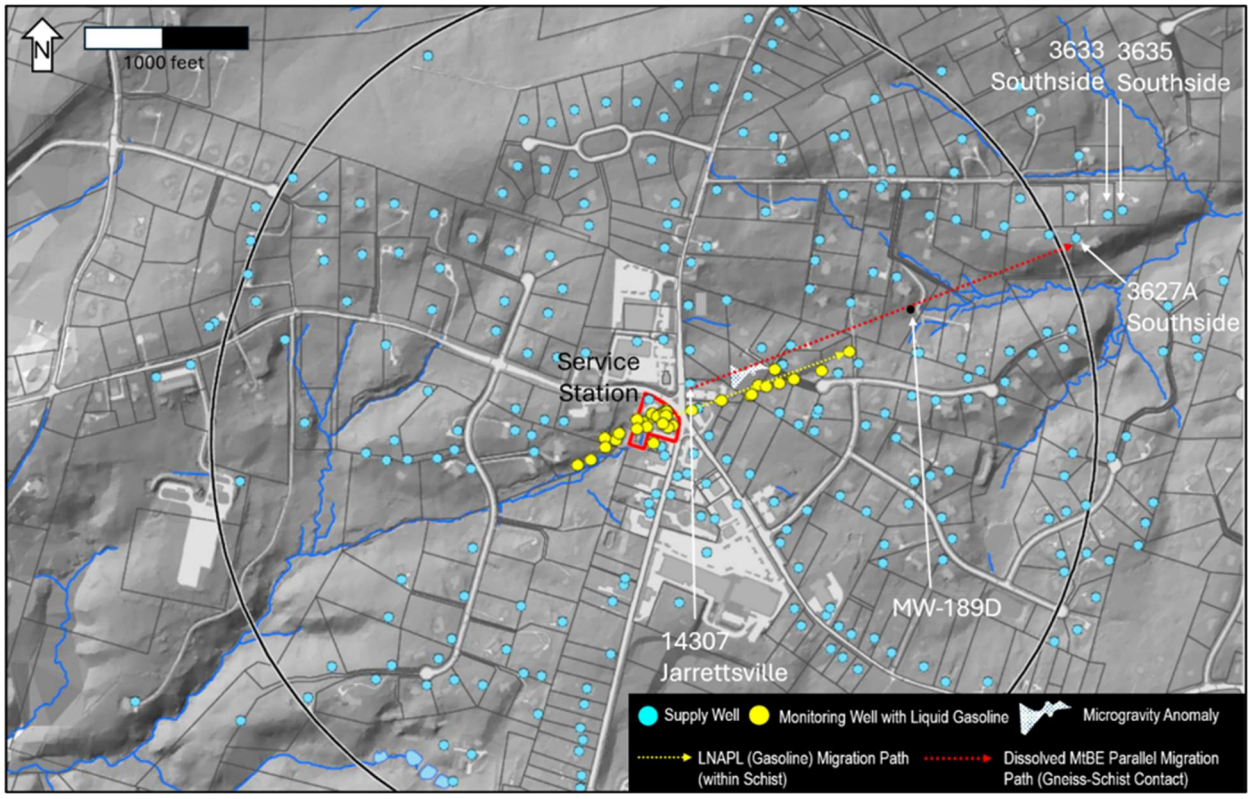
Hydrogeology, Fate, and Transport

General Framework and Processes

- The groundwater potentiometric gradient is toward the topographic valleys extending northeast and southwest from the former service station property (convergence from the valley sides and from below). Groundwater (un-impacted) discharges to tributaries of the Sawmill Branch of Little Gunpowder Falls and the Greene Branch of Gunpowder Falls.
- Influenced by the anisotropy of the metamorphic foliation and constrained by the aforementioned converging potentiometric gradient, liquid-phase hydrocarbons (LPH) and dissolved-phase hydrocarbons migrated along strike, coincident with the longitudinal axis of the topographic valleys extending from the former service station property (Graphic ES 1). This migration principally occurred in the shallow groundwater (water table) interval.
- Private supply wells are generally not installed within the topographic valleys (Graphic ES 1).
- Vertical downward migration of LPH and dissolved-phase hydrocarbon is impeded by several factors:
    - Gasoline is a non-aqueous phase liquid with a specific gravity less than water (i.e., LPH).
    - There is an upward hydraulic gradient beneath the topographic valleys extending northeast and southwest from the former service station property.
    - The porosity, permeability, fracture frequency, and fracture aperture decrease with depth in the fractured rock aquifer with maximum permeability occurring near the water table in the shallow weathered transition zone between saprolite above and more competent bedrock below.
    - Groundwater extraction for remediation has inhibited vertical downward migration and has instead induced an upward hydraulic gradient in remediation areas.

© 2026 Kleinfelder

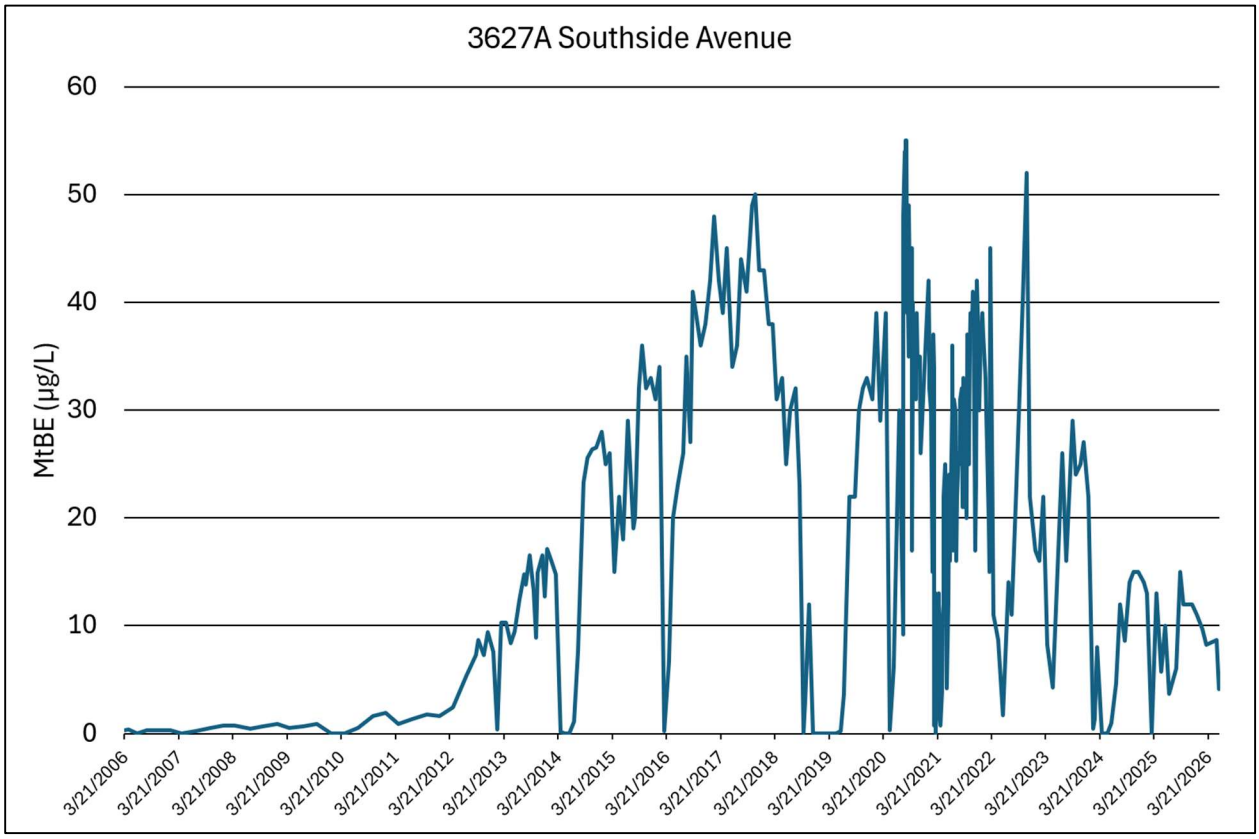
Graphic ES 1 Geologic map with well locations and historic extent of liquid phase hydrocarbon (LPH).



Distal Northeast

Increasing MTBE concentrations were identified in the distal northeast private supply well at 3627A Southside Avenue leading up to the submission of the July 15, 2016 CSM Report (maximum concentration of 36 µg/L on October 6, 2015 prior to CSM submission). The azimuth from inactive Exxon service station to the 3627A Southside Avenue private supply well generally corresponds to the strike of metamorphic foliation in bedrock and is aligned with the previously demonstrated geophysical anomaly corresponding to a geologic contact between gneiss and schist (Graphic ES 2).

Subsequent investigation and evaluation through 2026 indicates that a pulse of dissolved MTBE migrated through distal northeast private supply wells at 3627A and 3635 Southside Avenue (Graphics ES 3 and ES 4). This pulse migrated along bedrock strike parallel to, but off-set from, the original line of LPH and MTBE migration, beyond the groundwater capture zone. This is attributed to early, near-source, down-dip entrainment by the private supply well at 14307 Jarrettsville Pike. The pulse of MTBE experienced



© 2026 Kleinfelder

diminishing concentrations along its flow path due to dispersion. The pulse peak has since passed through the supply wells at 3627A and 3635 Southside Avenue, and average MTBE concentrations have decreased since 1Q 2020. The MTBE concentration attenuated to less than the State Action Level of 20 µg/L prior to the pulse peak reaching the supply well at 3635 Southside Avenue and is not expected to migrate farther to the northeast above the action level. This fate and transport is further illustrated in the body of the report.

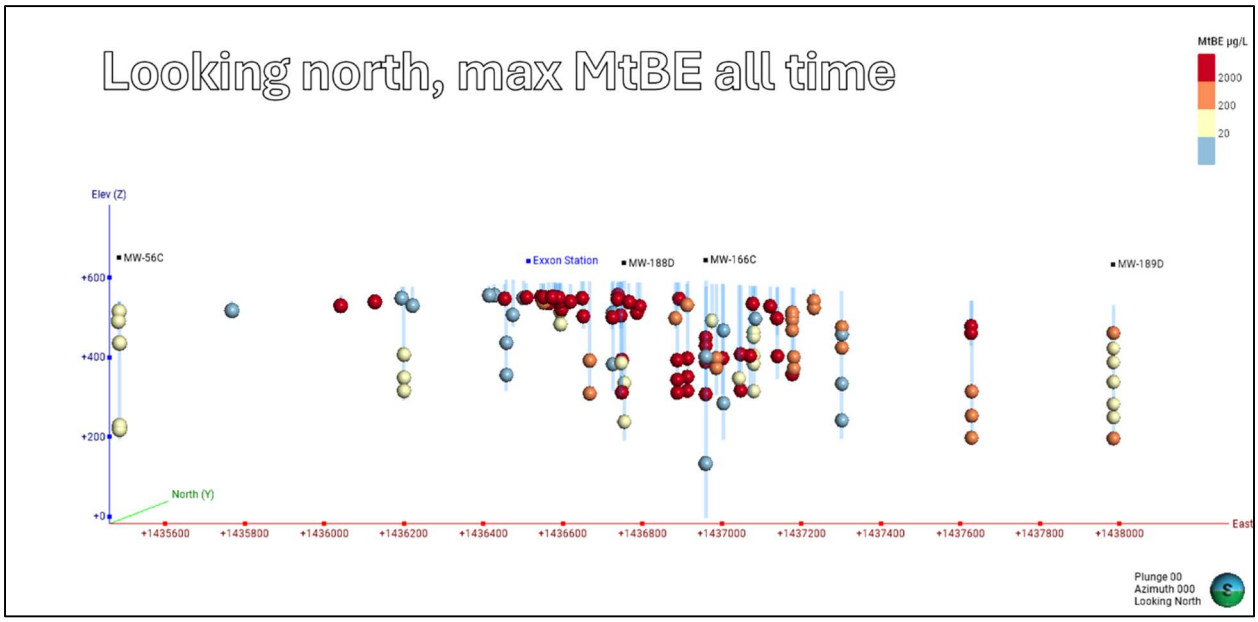
Graphic ES 4 MTBE concentration over time (2006 to 2026) for 3635 Southside Avenue

Natural Attenuation

The potential for natural attenuation involving microbial biodegradation in shallow and deep portions of the aquifer is indicated based on the following observations and conditions:

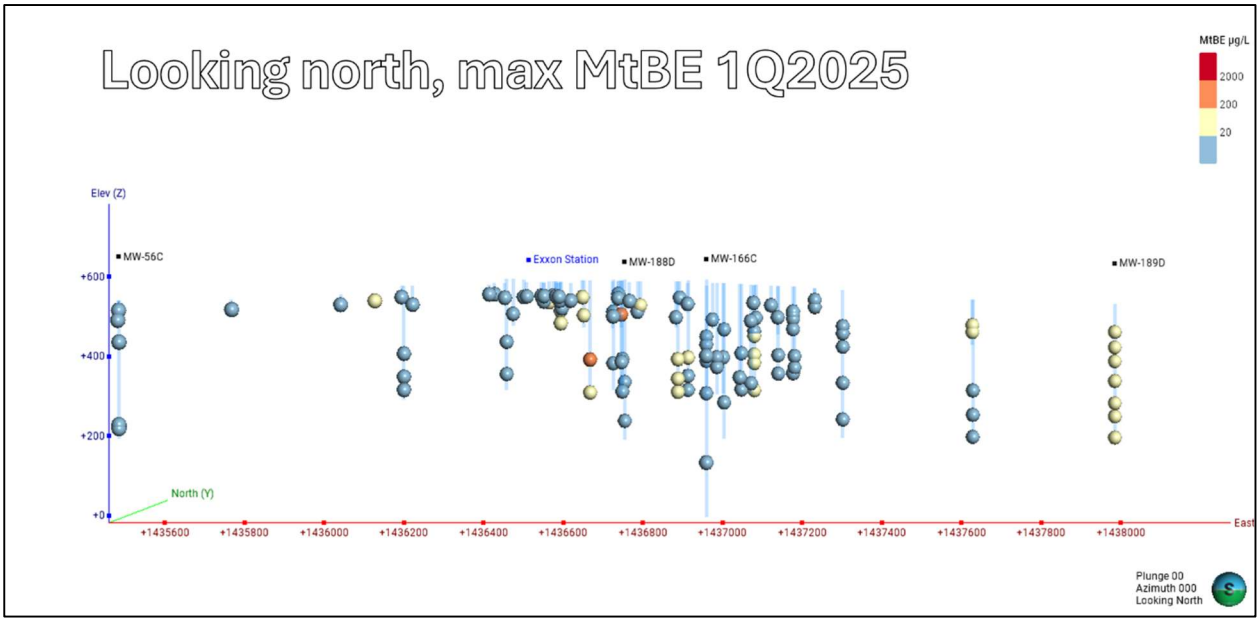
- There is an abundance of MTBE and BTEX degraders present throughout the aquifer, especially aerobic degraders.
- Microbial environmental conditions (temperature and pH) are within the optimal range for microbial activity, and the microbial nutrient, orthophosphate, is available.
- Stable Isotope Probing indicates:
    - MTBE was incorporated into microbial biomass and metabolized in certain monitoring wells.
    - Benzene was incorporated into microbial biomass and metabolized in the MW-54C sample.



© 2026 Kleinfelder

- Oxygen is available for aerobic biodegradation:
    - Positive ORP conditions exist throughout much of the aquifer.
    - The shallow zone is replenished with oxygenated water through recharge and water table fluctuation.

Response to Remediation



- The combination of total fluids pumping, multi-phase vacuum extraction, and soil vapor extraction was effective at removing LPH and dissolved-phase mass while containing and contracting the extent of dissolved-phase hydrocarbons in groundwater, resulting in system shutdown approval in December 2023.
- LPH that once extended in a linear, northeast-southwest direction over a distance of 1,870 feet has not been measurable in any of the more than 300 monitoring and recovery wells since 2008.
- Dissolved-phase hydrocarbons in groundwater have been significantly reduced in concentration and retracted in extent due to remediation activities.

Graphic ES 5 and ES 6 illustrates all time maximum and recent (1Q2025) maximum MTBE concentrations throughout the site from southwest to northeast, including discrete depth concentrations.

Graphic ES 5 Maximum MTBE concentration from all time looking north

© 2026 Kleinfelder

Graphic ES 6 Maximum MTBE concentration in 1Q2025 looking north

Recent Conditions

Recent MTBE concentrations throughout the site from southwest to northeast, including discrete depth concentrations are illustrated in Graphic ES 6 and summarized, as follows:

Inactive Station and Properties West of Intersection

Collectively, the groundwater conditions at the inactive station and other properties west of the intersection have significantly improved following approximately 18 years of active remediation. Most of the wells west of the intersection have remained consistently below standards throughout the post-remediation period. Of the wells that have had at least one detection above standard since system shutdown, concentrations have since subsided or stabilized at levels that do not indicate remaining source or migration pathways of concern.

Intersection and Adjacent Properties East of Jarrettsville Pike

The intersection and adjacent properties east of Jarrettsville Pike is where the highest concentrations remain. This is the area immediately downgradient from the UST release area where direct remediation within the intersection was delayed until the intersection reconstruction project was completed by SHA in 2014. The interior location of these isolated, residual concentrations limits risk of migration to potential receptors.

© 2026 Kleinfelder

Northeast Properties

There are 15 monitoring wells remaining on properties to the northeast, including 3501, 3506, and 3508 Hampshire Glen Court, and 3605A Southside Avenue, as well as six PSWs which continue to be sampled. Ten of these monitoring wells have been consistently below standards throughout post-remediation monitoring and earlier. The other 5 monitoring wells have had at least one detection above standard since system shutdown. Since 2022 trends in MTBE concentrations at MW-47C and MW-82D appear to be increasing though established trigger levels have not been exceeded, while trends appear to be stabilizing or decreasing at the three remaining wells. Six properties in this area have in-use PSWs which are currently sampled: 3506, 3508, and 3600 Hampshire Glen Court, and 3605A, 3627A, and 3635 Southside Avenue. PSW sampling results for all of these properties except 3627A Southside Avenue have been below MDE drinking water standards for at least 17 years.

Concentration Trends and Risk Summary

It is well understood where potentially complete exposure routes of concern remain, comprised of a potential source (elevated MTBE or benzene groundwater concentrations), potential migration pathway, and potential receptor (private supply well). At monitoring wells where concentration increases occurred following system shutdown and re-equilibration within the aquifer, most have since stabilized or decreasing trends have been established. At the few locations which currently exhibit potential increasing trends, these concentrations are generally consistent with historic levels in the vicinity, and it is expected that future trends will level off and then ultimately decrease aided by natural attenuation since most of the source has already been removed.

Additionally, it is understood where there is no longer a potential exposure of concern due to lack of either source, demonstrated migration pathway, or potential receptor. This understanding should inform site management decisions going forward as monitoring should continue in areas of potential concern and can cease in locations without a potential exposure of concern.

This approach is consistent with literature and scientific consensus on remediation and natural attenuation of petroleum release sites, including USEPA's *Reassessing Exposure Threats from Petroleum Underground Storage Tank Releases* (EPA OUST, 2025) and ASTM *Standard E3488-25 Moving Sites to Closure (MStC) for Petroleum Underground Storage Tank (UST) Releases* (ASTM 2025). Petroleum plumes tend to naturally stabilize and degrade and contract instead of expand and increase, particularly when

© 2026 Kleinfelder

there is limited source strength such as the case for this site following extensive remediation and indication of natural biodegradation, and monitoring of areas with low potential threat to receptors is unnecessary.

Path Forward Proposal

Based on the conceptual model, recent conditions, and concentration trends, continued monitoring of key monitoring and supply wells in focused locations is proposed. Monitoring wells proposed for continued monitoring include six wells in the intersection area (MW-187A, MW-187B, MW-187C, MW-54, MW-54B, and MW-54C), and four wells within the Hampshire Glen and Southside Avenue neighborhoods (MW-47C, MW-82B, MW-82D, and MW-189D). Private supply wells at four properties are proposed for continued monitoring, including 14307 Jarrettsville Pike, 3506 Hampshire Glen Court, 3627A Southside Avenue, and 3635 Southside Avenue.

Multiple other monitoring wells and supply wells are proposed for discontinuation of sampling, including monitoring wells proposed for abandonment. The following bullets summarize the proposed modifications to the existing sampling program:

- 292 total abandoned monitoring wells
- 13 monitoring wells retained
    - 10 sampled quarterly
    - 3 retained but not sampled
- 4 supply wells retained for quarterly sampling

Parcel-specific no further action is requested for 3410 Sweet Air Road and 3418 Sweet Air Road. MDE has approved cessation of all remediation and monitoring activities at these properties, including abandonment of all monitoring wells. Monitoring well abandonment records have been submitted to the Baltimore County Health Department, with copies provided to the MDE.

© 2026 Kleinfelder

1 INTRODUCTION

This report is provided to the Maryland Department of the Environment Oil Control Program by Kleinfelder on behalf of ExxonMobil for inactive Exxon retail station #28077 (MDE Case Number 2006-0303-BA2) located at 14258 Jarrettsville Pike in Phoenix Maryland (Figure 1) to satisfy the MDE's request for an updated CSM in their May 1, 2026 letter, *Discrete zone sampling MW-178C and MW-184 Approval and Request for Updated CSM*.

Extensive site characterization, remediation, and monitoring activities have been conducted by ExxonMobil under the direction of the MDE upon detection of a release of unleaded gasoline at the former service station in 2006.

The purpose of this document is to consolidate and summarize key findings of site characterization, monitoring, and remedial activities conducted to date, including findings from the past two and a half years of post-remedial monitoring, and consolidate this information into an updated conceptual site model (CSM). The CSM is intended to inform the appropriate degree of monitoring, remediation, reporting, and modifications to ensure protection of the environment and potential receptors while progressing the case towards and MDE issuance of No Further Action (NFA). In addition to the Updated CSM, this report also includes recommendations in the form of a work plan for future activities, and outlines a proposed path to NFA issuance and closure of Case Number 2006-030-BA. As such, this document will facilitate MDE's determination when no further action is warranted for protection of public health and the environment per paragraph 34 of the 2008 Consent Decree.

The report is organized into the following sections:

Section 2.0 – Site Description and Setting
This section provides the area context for the project including location and surrounding land use.

Section 3.0 – Current Monitoring and Remediation Status
Extensive investigation and remediation activities have been conducted since the inception of the project in February 2006. The last CSM Report was submitted in 2016, and the project has been in post-remediation monitoring since December 21, 2023. This section summarizes the investigations and

© 2026 Kleinfelder

remedial actions, highlighting work completed since the 2016 CSM Report, and the progression to remediation system shutdown and post remediation monitoring, and references the associated documentation that serves as the basis of the CSM described herein.

Section 4.0 – Conceptual Site Model

The CSM is documented in this section, including, the Site's physiographic and topographic setting, and underlying geology and hydrogeology, descriptions and visual presentations of 1) contaminant phases and affected media; 2) source, pathways, and potential receptors; 3) hydrogeologic framework; 4) response to remediation and remedial effectiveness; 5) summary of post-remediation site conditions and groundwater quality; and 6) alternate source impacts.

Section 5.0 – CSM Conclusions

Key findings of the CSM are presented as conclusions in this section.

Section 6.0 – Proposed Path to Closure

A series of next steps to advance the case to no further action approval are presented in this section, including proposed alternative groundwater criteria for discontinuation of monitoring well sampling and abandonment, based on site conditions, the CSM, and industry guidance.

© 2026 Kleinfelder

2 SITE DESCRIPTION AND SETTING

The 1.71-acre former service station property is located at 14258 Jarrettsville Pike, on the southwest corner of the intersection of Sweet Air Road/Paper Mill Road (MD 145) and Jarrettsville Pike (MD 146) in Phoenix, Baltimore County, Maryland (Figure 1).

Local businesses (retail and commercial concerns) are concentrated around this intersection (Figure 2), including a retail petroleum distributor across Jarrettsville Pike to the east. Beyond this "business district" the land use is primarily single-family residential properties interspersed with some vacant, undeveloped lots and wooded areas (Figure 2). Sewage in the area is managed by private septic systems and sewage disposal is handled by septic tank waste contractors. Water is obtained from private supply wells (Figure 3).

© 2026 Kleinfelder

3 CURRENT MONITORING AND REMEDIATION STATUS

3.1 ACTIVITIES COMPLETED SINCE 2016 CSM

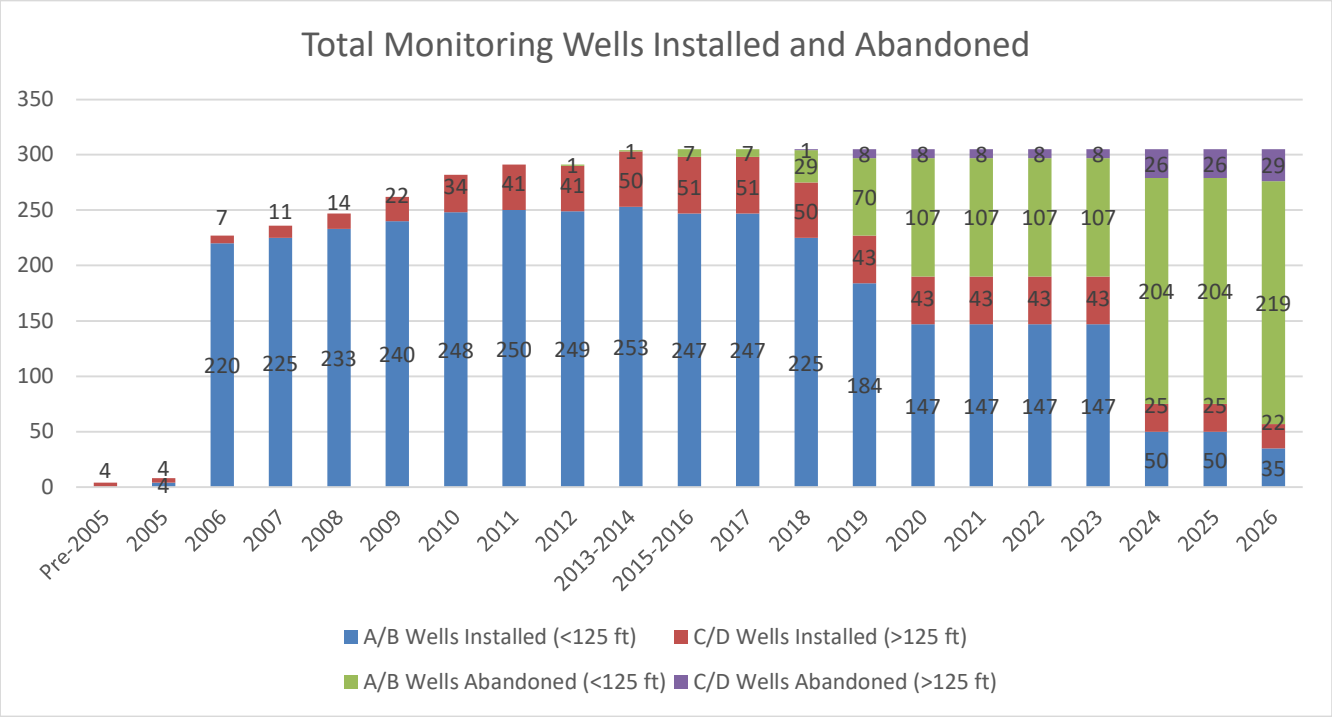
Since submittal of the July 15, 2016 CSM Report, numerous activities have been completed for protection of public health and the environment, and to progress the case towards closure, including implementing recommendations from the 2016 CSM Report. Key activities and associated documents are summarized below.

- Monitoring Well MW-189D was installed on December 16, 2016 as proposed in the 2016 CSM Report to evaluate concentrations at the 3627A Southside Avenue private supply well, as reported in the June 22, 2017 *Well Installation Report for MW-189D*. Based on the detection of gasoline related constituents in MW-189D consistent with detections in the downgradient supply well, the 3627A Southside supply well has been retained in the conceptual model. Additional downhole investigation of MW-189D was completed in 2018 as reported in the *Report of Results – Transducer Installation – Supply Well at 3627A Southside Ave. and Pumping Test – MW-189D.*
- On June 8, 2018 the State of Maryland and Exxon Mobil Corporation resolved the dispute as documented in the *Order of Resolution of Petitioner's Petition for Enforcement of Consent Decree and for Judicial Review* (Circuit Court of Maryland for Baltimore County, 2018). Per the 2018 Order of Resolution, the parties agreed to: 1) discontinuation of the bottled water delivery program; 2) reductions in required private supply well sampling; 3) reductions in required Point-of Entry Treatment (POET) systems to be maintained by ExxonMobil; 4) review timeframes for workplans submitted by ExxonMobil to MDE; and 5) establishing flowcharts to aid MDE consideration of proposals by ExxonMobil for certain case progression activities, including conversion of a recovery well to a monitoring well, abandoning a monitoring well, discontinuation of private supply well sampling and conveyance or removal of POETs, and property-specific No Further Action determination.
- From 2018 through 2026 the status of monitoring and recovery wells was modified based on response to remediation, the low magnitude of certain residual concentrations, and concentration trends, consistent with the 2018 Order of Resolution Flowcharts 1 and 2. Specifically, all 63 remaining recovery wells were progressively repurposed as monitoring wells, and 241 monitoring wells were abandoned. (*Monitoring well abandonment records could not be located for two monitoring wells that were approved for abandonment by MDE in their June 25, 2020 letter Approval of Monitoring Reduction and Well Abandonment. Monitoring well MW-69 was approved for abandonment but could not be located during recent field inspection, and the status of MW-69 will be further investigated. MW-77R was approved for abandonment, however*

© 2026 Kleinfelder

during recent field inspection was located and inspected, and appears to be intact. Abandonment of these wells will be completed per Maryland regulations following further investigation of status.)

- From 2018 through 2025 the private supply well sampling program has been reduced to 15 properties, and the number of POETs maintained by ExxonMobil has been reduced to one, as approved by MDE, consistent with the 2018 Order of Resolution Flowchart 3.
- In 2017 and 2019, parcel-specific NFAs were granted at three properties, 14209 Robcaste Road, 14222 Jarrettsville Pike, and 14231 Jarrettsville Pike consistent with the 2008 Consent Decree and 2018 Order of Resolution Flowchart 4.
- On July 25, 2019, Kleinfelder, on behalf of ExxonMobil, submitted a Natural Attenuation Evaluation Report (Kleinfelder, 2019) to MDE, indicating potential for microbial biodegradation in shallow and deep portions of the aquifer.
- Detailed vertical characterization and concentration profiling was conducted at the 3627A Southside Avenue private supply well. Sequentially, this included borehole geophysical profiling, discrete interval HydraSleeve™ sampling, and short-term well purging and sampling. Documentation of these activities is presented in the following reports: *HydraSleeve™ Sampling Proposal – 3627A Southside Avenue Supply Well (Kleinfelder, 2017a), Report of Results: Pump Test in MW-78C; HydraSleeve™ Sampling – 3627A Southside Avenue Supply Well; and Low-Flow Sampling in MW-189D* (Kleinfelder, 2017b) and *3627A Southside Avenue Purge Test – Report of Results* (Kleinfelder, 2022).
- A biosparge field pilot test was conducted to evaluate lines of evidence indicating biosparging can enhance the activity and effectiveness of biodegradation of constituents of concern (COCs). This pilot test is documented in the *Biosparge Pilot Test Report and Work Plan* (Kleinfelder, 2020). The biosparge pilot test was conducted for approximately six months using monitoring well MW-91C for injection of air into groundwater. Monitoring wells MW-91, MW-183 [R], MW-184 [R], and MW-185 [R] were used as primary observation wells. Other wells monitored during the pilot test included MW-47C, MW-138D [R], MW-168, MW-171C, MW-176 [R], and MW-177. The results demonstrated positive indication of biodegradation potential and evidence of biodegradation activity.
- Operation of active remediation systems ceased with MDE approval due to low recovery rates, improved groundwater concentrations, and limited benefit of continuing to operate the remediation systems while natural attenuation is evident. This included shutdown of vapor extraction systems in April 2017 (Trilobe SVE) and April 2020 (DPE system), and following conversions of most recovery wells to monitoring wells and two rounds of cycling assessments with the remaining 14 and then 4 recovery wells in 2022 and 2023, respectively, the groundwater recovery system was shut down on December 21, 2023.



© 2026 Kleinfelder

- Additional discrete depth sampling was conducted, and 3D visualization graphics were prepared from 2024 into 2025. This information is documented the *Discrete Depth Sampling Results, Sampling Modification, and Well Abandonment Work Plan* (Kleinfelder, 2025).

3.2 CURRENT MONITORING / RECOVERY WELL NETWORK

The existing monitoring well network is comprised of 51 monitoring wells. Since 2006, 252 monitoring wells have been abandoned following MDE approval (including 4 abandoned boreholes which were never completed as wells), and 4 unused private supply wells which were used as monitoring wells were approved for sampling cessation. Two additional monitoring wells have been approved for abandonment, however abandonment records have not been located and abandonment will be completed as required pending further investigation. The majority of the wells were installed in the first year of investigation with additional groups of wells installed over time to address specific data needs or requests. Since 2017 well abandonments have been approved as remediation progressed and certain monitoring wells were considered redundant. Following the Dispute Resolution Order in 2018 that established flowcharts to streamline the criteria for progressing the case, including converting recovery wells to monitoring wells, and abandoning monitoring wells, recovery well conversions and well abandonments proceeded with MDE approval according to the criteria and processes outlined in the Flowcharts. The timeline of well installations and well abandonments by year is presented in Graphic 1. A summary of historical investigations and assessment activities can be found in Appendix A and a summary of historical remediation activities is provided in Appendix B.

© 2026 Kleinfelder

Graphic 1: Cumulative Number of Monitoring Wells Installed and Abandoned by Year.

Currently, 51 monitoring wells are sampled, including 25 sampled quarterly and 26 sampled semi-annually, according to the MDE's February 2, 2026 *Select Monitoring Well Abandonment Approval*. Additionally, certain wells are sampled monthly if they exhibit concentrations above the trigger levels for MTBE or benzene that were established as a condition of the MDE's December 19, 2023 *Post Remediation Monitoring Plan Approval.* Groundwater monitoring results are provided in quarterly *Groundwater Monitoring Reports* (Kleinfelder, 2026).

Monitoring Well Network Distribution

The existing monitoring well network is shown on Figure 4. Project monitoring and remediation wells were installed to generally correspond to four relative depths:

- A zone – Shallowest wells screened across the water table (or close to it). Historical detection and remediation of LPH occurred in the A Zone monitoring wells (up to 60' total depth).
- B zone – Wells that typically have submerged well screens or open intervals beneath A zone and are approximately 125' in total depth.
- C zone – Relatively deep wells installed to depths comparable to areas supply wells. Depths of approximately 300 feet are typical for C zone wells.

© 2026 Kleinfelder

- D zone – Deepest project monitoring wells intended to characterize groundwater conditions beneath the depth of area supply wells. D zone wells can be as deep as 400 feet.

The relatively deeper wells case off the shallower, letter-designated intervals. Monitoring well construction details are summarized in Appendix C and monitoring well construction logs are provided in Appendix D. Many of the B, C and D wells have been sampled via HydraSleeve to collect data from discrete depths within the water column. In some cases, the specific depths selected for sampling via HydraSleeve are based on fractures or other zones of interest identified during downhole geophysics, packer testing and subsequent sampling. In other cases, shallow and deep HydraSleeve samples are collected from a well to provide data from the upper and lower portions of screened or open intervals, where the Shallow sample is collected from approximately the middle depth of the top half of the screen / open hole, and the Deep sample is collected from approximately the middle depth of the lower half of the screen / open hole. An overview of the HydraSleeve sampling program and findings from additional HydraSleeve sampling conducted in 2024 and 2025 were presented in Kleinfelder's June 4, 2025 *Discrete Depth Sampling Results, Sampling Modification and Well Abandonment Workplan* along with a proposal to reduce the number of sampled HydraSleeve intervals. As presented in the June 4, 2025 *Workplan*, HydraSleeve sampling results have generally been consistent with results from purge and grab sampling, and samples from one to three discrete depths (depending upon the well) provide sufficient resolution of groundwater concentration trends across the vertical profile. The current HydraSleeve sample intervals were approved by the MDE in the February 2, 2026 *Select Monitoring Well Abandonment Approval* and the MDE's May 1, 2026 letter.

3.3 CURRENT SUPPLY WELL SAMPLING PROGRAM

The current MDE-approved PSW sampling program includes sampling of 15 supply wells, including 1 supply well sampled monthly, 3 additional supply wells sampled quarterly, and 11 supply wells sampled semi-annually in accordance with MDE's February 18, 2025 *Response to Potable Supply Well Sampling Reduction Work Plan*, September 19, 2025 *Requirement to Continue Sampling* and September 24, 2025 *Approval to Discontinue Sampling Select Potable Supply Wells*, respectively. Since January 2013, only one supply well sampled on behalf of ExxonMobil (3627A Southside Avenue) has had detections of gasoline constituents (BTEX, five fuel oxygenates including MTBE or naphthalene) above regulatory standard, and the last detection above the MDE standard at this location was in January 2024. ExxonMobil currently maintains a point-of-entry (POET) system at 3627A Southside Avenue.

4 CONCEPTUAL SITE MODEL

This section integrates the chemical, geologic, and hydraulic information obtained from the multiple investigative and monitoring activities conducted into a CSM that describes the following site characteristics and conditions:

- Contaminant phases and affected media;
- Source, pathways, and potential receptors;
- Hydrogeologic framework;
- Response to remediation and remedial effectiveness;
- Summary of conditions and groundwater quality; and,
- Alternate sources of impacts.

4.1 PHYSICAL SETTING

This section describes the physical setting and underlying geological framework in the project area. The area hydrogeology and physiography are described first followed by the geologic framework, which is related to the surface expression of topography and physiography.

4.1.1 Topography and Physiography

The site exists within Piedmont Physiographic Province of Maryland (Schmidt, 1993). The topography (Figures 1 and 5) is closely related to the geology of the region (e.g., foliated bedrock structure and differential weathering) (Figure 6). The local topographic features depicted on Figures 1 and 5 (e.g., drainages that trend southwesterly and northeasterly away from the service station property, and the ridge upon which the service station property is located) are geomorphic expressions of the underlying bedrock surface and structural orientation (Figure 7). The topographic features observed (the drainages and ridges) are also roughly parallel to the strike of the bedrock foliation, again northeast-southwest.

These streams have formed by eroding into a weak zone within the bedrock which is generally parallel to the foliation of the rock. These are referred to in the literature as “strike streams” (Strahler, 1960), because they are linear and trend along strike of the bedrock foliation.

© 2026 Kleinfelder

4.1.2 Geology

The project area is underlain by metamorphic rocks comprising the southern flank of the Phoenix Dome, regionally mapped by Moller (1979) as the Loch Raven Schist of the Wissahickon Group (Figure 6). Sub-units encountered during the investigation included gneiss and pegmatite. The bedrock types encountered during the investigation are consistent with historical regional mapping.

The primary bedrock structural feature is the metamorphic foliation, which is mapped to strike northeast and dip northwest (Moller, 1979). This structural orientation is consistent with geologic observations, manual measurements, and borehole geophysical measurements of the foliation orientation completed as part of this investigation.

Graphic 2: Bedrock foliation looking southwest in tank field excavation.

Conformably overlying bedrock is a layer of saprolite (Cleaves, 1974), which forms a gradational weathering profile with bedrock.

The soils encountered during the site investigation overlay the saprolite and are generally composed of silty to sandy clay and clayey to silty sand. The thickness of the overburden (soils and saprolite) across the area ranges from 5 feet (higher elevations) to 65 feet (drainage channels and lower elevations). Soils in the region are primarily considered moderately eroded Glenelg Loam (GcB2 and GcC2) with lesser amounts of moderately to severely eroded Manor Loam (MbB2, MbC2, MbC3, and MbD3) occurring on some of the steeper slopes

Graphic 3: Relict foliation in saprolite from tank field test pit.

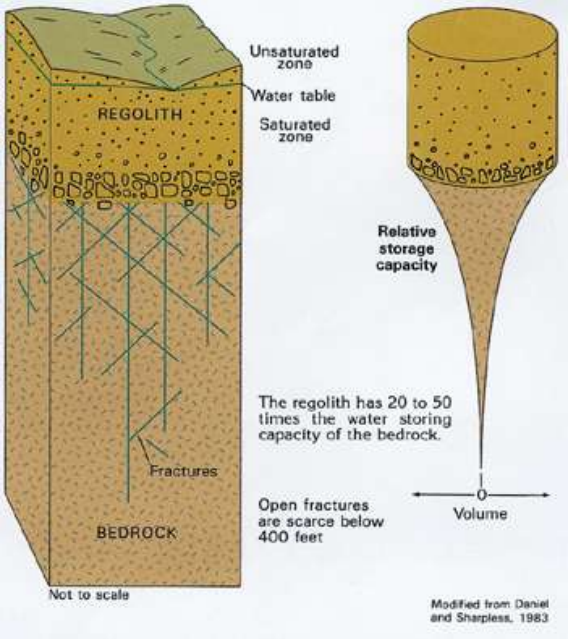
© 2026 Kleinfelder

(Reybold, 1976). There are minor amounts of Glenville Silt Loam (GnB) limited to the drainage areas of the project. These soil types are deep, variable in the degree to which they drain, and may exhibit moderate permeability. These soils are consistent with the soils encountered during the investigation.

4.2 HYDROGEOLOGY

4.2.1 Hydrogeologic Setting

The Piedmont Physiographic Province is characterized by bedrock aquifers within metamorphic and igneous rocks of the region (Nutter, 1974). Primary (intergranular) porosity of the bedrock is relatively minimal compared to the secondary porosity (fractures, joints, foliation, etc.) of the bedrock, in which groundwater flow may occur. The spacing and extent (persistence) of the fractures, joints, and foliation affect the availability of groundwater within the bedrock aquifer. Groundwater within the bedrock is generally restricted to flow within the network of fractures, joints, and foliation. Regionally and at distal locations in the project area, the groundwater table may occur above or within the weathered bedrock transition zone or within the saprolite; these zones transmit groundwater where saturated. Fractures, joints, and foliation aperture decrease with depth (i.e., the bedrock is increasingly more competent with depth), resulting in diminished downward vertical movement of groundwater.



4.2.2 Hydrogeologic Framework

Within area bedrock aquifers, groundwater generally occurs under water table (unconfined) conditions. Locally, the top of bedrock surface may exist at an elevation above that of the water table (Figures 20a and 20b). In these areas, groundwater occurs and moves exclusively within the secondary porosity of the bedrock – the fractures, joints and foliation. The water table may also occur within the weathered residuum (saprolite or soil) above bedrock (Figures 20a and 20b). Within the saprolite layer, groundwater occurs and moves within the pore spaces between the weathered mineral grains and within the relict foliation.

The depth to groundwater ranges from near the ground surface (approximately 3 feet bgs) northeast and southwest of the former service station property where the gaining streams occur to approximately 40 feet bgs beneath the former service station property in the vicinity of the former tank field (static depth to water, not pumping-induced). Stream channels in the study area have the thickest layers of saprolite and alluvial sediments, and groundwater occurs closest to the ground surface in those areas. The water table in areas of higher topography generally exists within bedrock.

© 2026 Kleinfelder

The embedded diagram, Graphic 4, illustrates the typical weathering and fracture profile for crystalline rocks within the Piedmont Physiographic Province. The diagram also illustrates the relationship of groundwater saturation and hydrogeology to the weathering and fracture profile. Specifically, the diagram indicates storage capacity and permeability are greatest near the saprolite-top of bedrock surface ("regolith") where there is more weathering, porosity, and greater fracture frequency. Conversely, open fractures decrease with depth with few, if any, open fractures below 400 feet from surface, indicating diminished storage capacity and permeability with depth.

Graphic 4: Typical weather and fracture pattern for crystalline rocks in the Piedmont Physiographic Province

4.2.3 Geologic Control of Groundwater Flow and Contaminant Migration

The direction of groundwater flow and contaminant migration is strongly influenced by the northeast-southwest trending strike of the foliation of the Loch Raven Schist, the formation comprising the bedrock aquifer. This resulting anisotropy influenced hydrocarbon migration (LPH and dissolved phase) to occur in a linear direction to the northeast and southwest. The direction of hydrocarbon migration was also influenced and constrained by the area topography and potentiometric surface, which is a subdued expression of the topography. This resulted in hydrocarbon migration that occurred within and is constrained to the erosional valleys extending to the northeast and southwest from the former service station property. Figure 8 illustrates the structural and topographic influence on hydrocarbon migration by superimposing the topography, underlying geology, and maximum historical extent of LPH migration. Figure 8 also includes surrounding supply wells, surface drainage features, and the monitoring and recovery well network. Inspection of this map (Figure 8) results in the following observations:

- LPH migration on the water table within the upper weathered and fractured portion of bedrock was linear to the northeast and southwest within the erosional valley that occurs along the foliation strike of the Loch Raven Schist.
- The maximum historical distribution of LPH is surrounded and delineated by the monitoring and recovery well network.

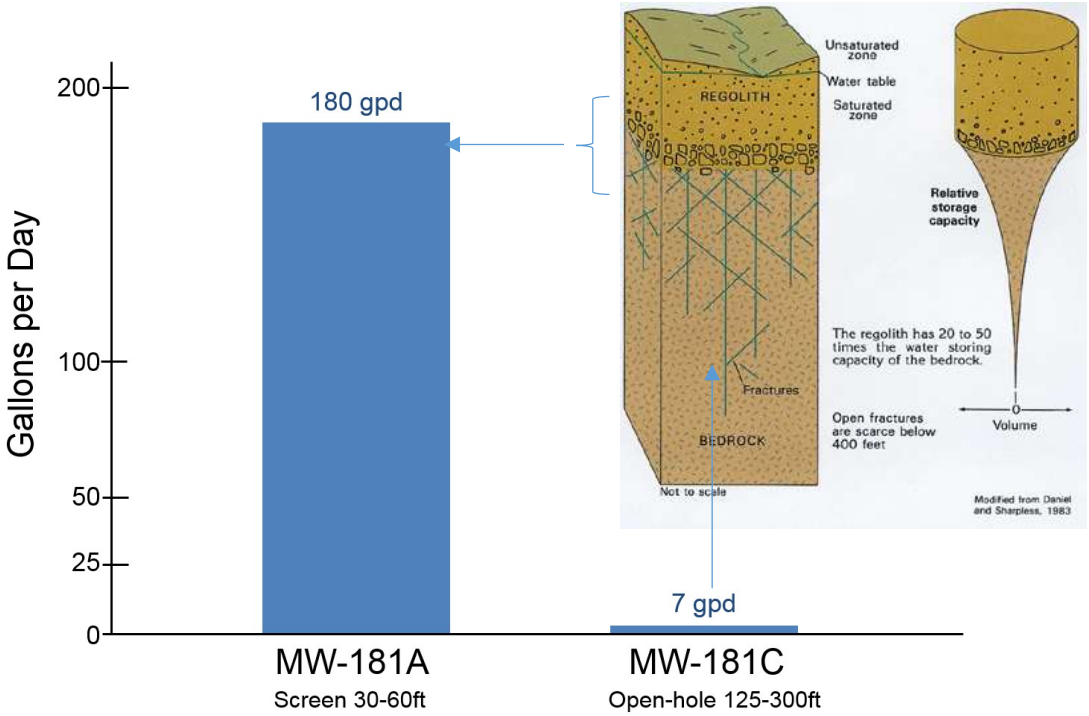
© 2026 Kleinfelder

- Surrounding supply wells are generally located peripheral to the historical extent of LPH migration and are generally not installed within the topographic valleys where LPH and dissolved phase hydrocarbon migration occurred.

Dissolved phase hydrocarbon distribution maps (Figures 9a to 9e) also exhibit generally linear dissolved phase migration due to anisotropy and related topographic / potentiometric influence.

A lineament trace analysis (Kleinfelder, 2008b) was conducted at the request of the MDE to identify the surficial expression of geologic, structural, and or topographic features that could potentially influence the direction of hydrocarbon migration relative to potential receptors in the area. Figure 10 presents a map illustrating potential lineaments in the area. The lineament trace analysis report concludes the potential for dissolved-phase migration to the regional lineament network is limited by the natural convergence of the potentiometric surface toward the "strike line" lineament, the hydraulic control maintained along the "strike line" and the paucity of cross-cutting lineaments that intersect the "strike line" in the vicinity of the project.

4.2.4 Hydrologic Influences on Groundwater Flow and Contaminant Migration



Potentiometric surface elevation maps (Figures 11a through 11c) exhibit the convergence of hydraulic gradients within the topographic valleys to the northeast and southwest, and the ultimate discharge of groundwater (un-impacted) to the headwaters of streams more distally located within the northeast and southwest stream valleys extending from the former service station property.

4.2.5 Vertical Profile of Hydrogeologic System

Vertical migration of hydrocarbons is inhibited by an upward vertical hydraulic gradient within the topographic valleys (Figure 12) where LPH and dissolved-phase hydrocarbons have been characterized and delineated. Vertical migration is further impeded by the diminishing frequency and aperture of fractures with depth in bedrock. The diminishing frequency and aperture of fractures with depth also results in lesser yield and lesser hydraulic conductivity with depth that is not conducive to vertical migration.

© 2026 Kleinfelder

The bar graph below illustrates the difference in groundwater recharge rate for a shallow monitoring well (Zone A) versus a deeper monitoring well (Zone C) at the MW-181 well cluster. The graph illustrates that groundwater recharge rate in the shallow (water table) zone is 26 times greater than the groundwater recharge rate for the deeper zone (Zone C); however, the open interval for the shallow zone monitoring well (MW-181A) is four times less than that of the deeper zone monitoring well (MW-181C).

Graphic 5: Decreasing storage, permeability, and transmissivity with depth in bedrock

Limited downward migration is also evidenced by chemical concentration data from the release area by comparing analytical results and LPH detection for shallow release area well MW-27 and deeper release area well MW-27B.

Monitoring Well	Open Interval (ft-toc)	Max MTBE (µg/L)	Recent MTBE (µg/L)	Comments
MW-27	27-43	869,000[1]	0.373[3]	Last well to contain LPH
MW-27B	60-125	120[2]	48[4]	

1) May 2007
2) June 2019
3) November 2025
4) April 2026

© 2026 Kleinfelder

Recent analytical results associated with the monitoring wells installed within the intersection of Paper Mill Road and Jarrettsville Pike also indicate limited vertical migration beneath the source near the release area. Elevated MTBE concentrations are noted in the intermediate depth zone, which is attributed to the hydraulic influence of the nearby private supply well at 14307 Jarrettsville Pike, which is discussed in more detail in the following section:

Monitoring Well	Open Interval (ft-toc)	MTBE (µg/L	Benzene (µg/L)
MW-187A[2]	25-60	17	330
MW-187B[2]	60-125	190	83
MW-187C[1]	125-300	160	2.3
Sampled May[1] 2026 and June[2] 2026			

4.2.6 Potentiometric Surface and Hydraulic Gradients

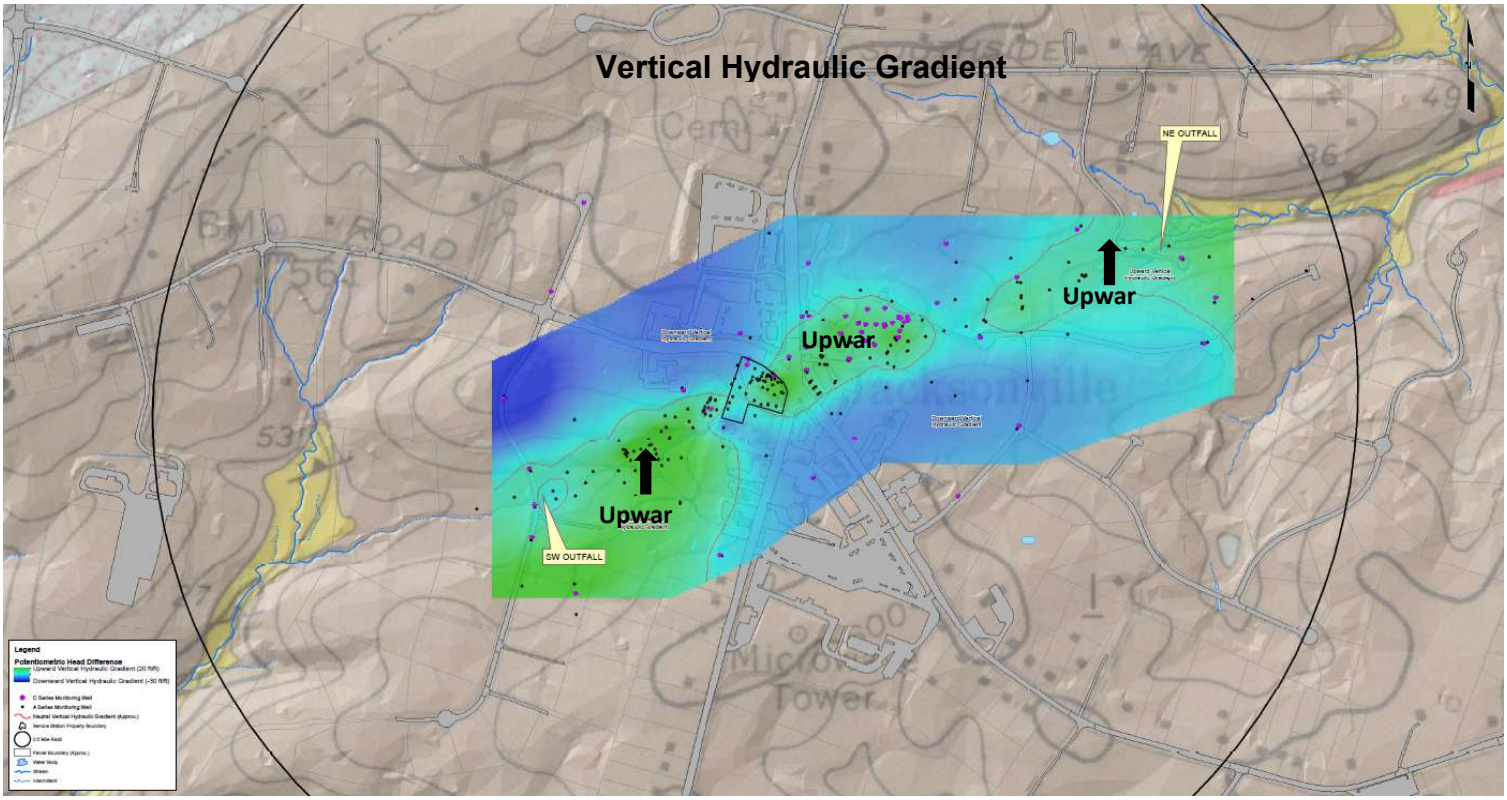
Figures 9a and 9b present the groundwater potentiometric surface relative to topography and geology. These maps include the water table surface (Zone A) for a range of groundwater extraction conditions during the course of remediation represented by groundwater gauging conducted during the autumn in 2010 and 2015. Monthly potentiometric surface elevation contour maps, including gauging data, have been submitted to the MDE in quarterly remedial action progress reports (RAPRs) submitted over the past 10 years. Figure 11c presents potentiometric surface elevation maps for deeper portions of the bedrock aquifer (Zone C) corresponding to April 2010.

Inspection of these maps (Figures 11a through 11c) indicates the groundwater potentiometric surface is consistently a subdued expression of the topography with higher potentiometric elevation corresponding to upland areas and lower potentiometric surface corresponding to valleys for the water table (Zone A) and for deeper portions of the aquifer (Zone C). The potentiometric surface elevation pattern is also consistent with the top of bedrock surface elevation contour map (Figure 7) indicating that the groundwater potentiometric surface and associated flow direction is influenced by weakness and erosion of bedrock expressed as bedrock topography. Groundwater consequently converges in and flows toward stream valleys, eventually discharging to the headwaters of the gaining streams (tributaries of the Green Branch [southwest] and Sawmill Branch [northeast]) incised within the eroded metamorphic foliation.

Comparison of the April 2010 potentiometric surface and elevations for Zones A, B, and C indicates the distribution of vertical hydraulic gradients within the aquifer.

© 2026 Kleinfelder

In February 2011, ExxonMobil proposed a vertical head study to isolate vertical intervals of the bedrock aquifer and obtain potentiometric measurements. The study used clusters of "A," "B," and "C" zone wells, as well as the installation of packers to subdivide the open boreholes of various "C" zone wells.



The Vertical Head Testing Report (Kleinfelder, 2011b) documents the following conclusions:

- The dominant vertical gradient between shallow and deep zones at upland locations is downward. This is consistent with expected infiltration and recharge and downward gradients associated with elevated topography / plateaus (Heath, 1983).
- The dominant vertical gradient between shallow and deep zones at locations proximate to the valley bottom/axis is upward. This is consistent with expected groundwater discharge and upward gradients associated with valley bottoms and surface drainage/streams (Heath, 1983).
- Valley side slope locations exhibit both upward and downward vertical gradients depending on the location with downward gradients being most common.

These conditions are illustrated on the Vertical Hydraulic Gradient Map (Figure 12) that represents the relative potentiometric elevation difference between the water table (Zone A) potentiometric surface and the deeper (Zone C) potentiometric surface:

- In the valleys (green areas), the potentiometric elevation for the deeper zone is higher than the potentiometric surface elevation of the shallow zone (upward gradient).
- In the uplands (blue areas), the potentiometric elevation for the shallow zone is higher than the potentiometric surface of the deeper zone (downward gradient).

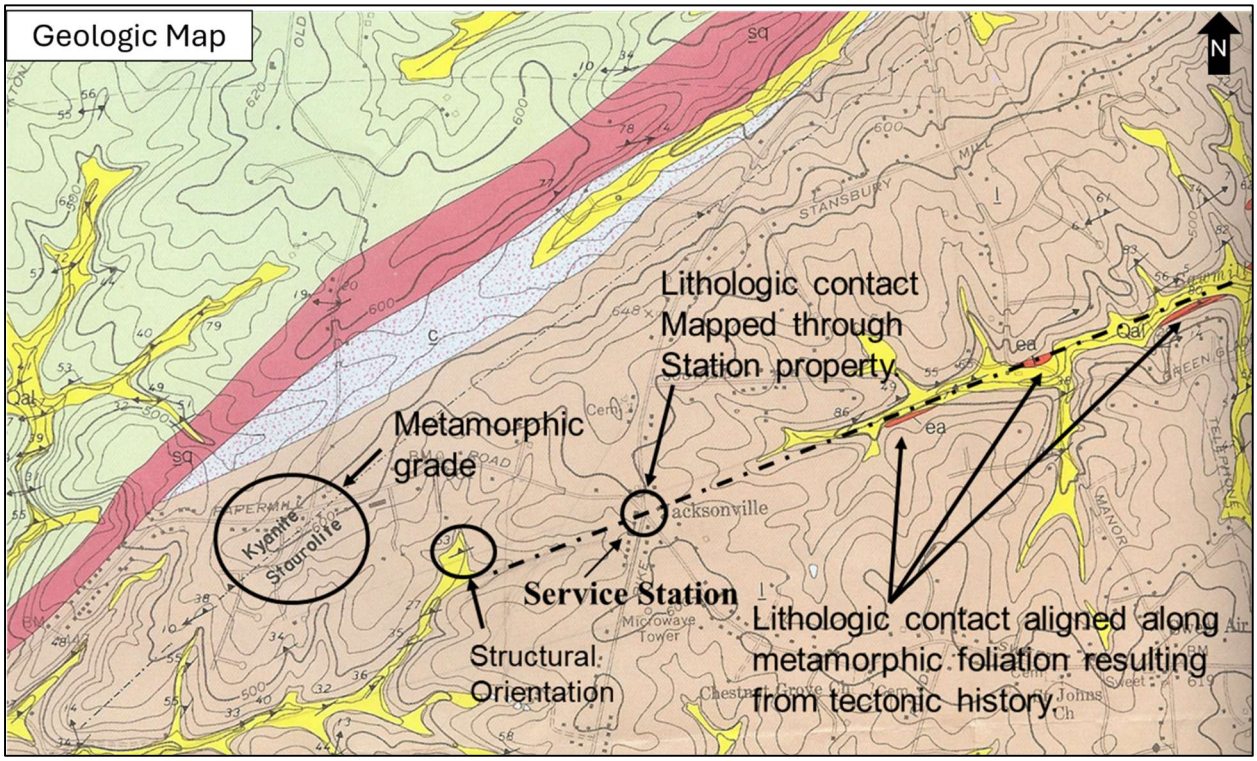
© 2026 Kleinfelder

Graphic 6: Vertical Hydraulic Gradient

4.2.7 Hydraulic Conductivity

Hydraulic conductivity was measured and calculated based on multiple slug tests and aquifer pumping tests, as documented in the Preliminary Hydrogeologic and Contaminant Assessment Report (Kleinfelder, 2006a). The hydraulic conductivity results are displayed and contoured on Figure 13. Inspection of this spatial presentation of hydraulic conductivity results reveals an elongate, longitudinal distribution pattern trending northeast-southwest with a core of greater hydraulic conductivity (8 to 28.9 ft/day) transitional to values of lesser hydraulic conductivity at the periphery (<1.0 ft/day). This pattern is generally coincident with the strike of the bedrock foliation and physiographic features (e.g., stream channels incised into bedrock).

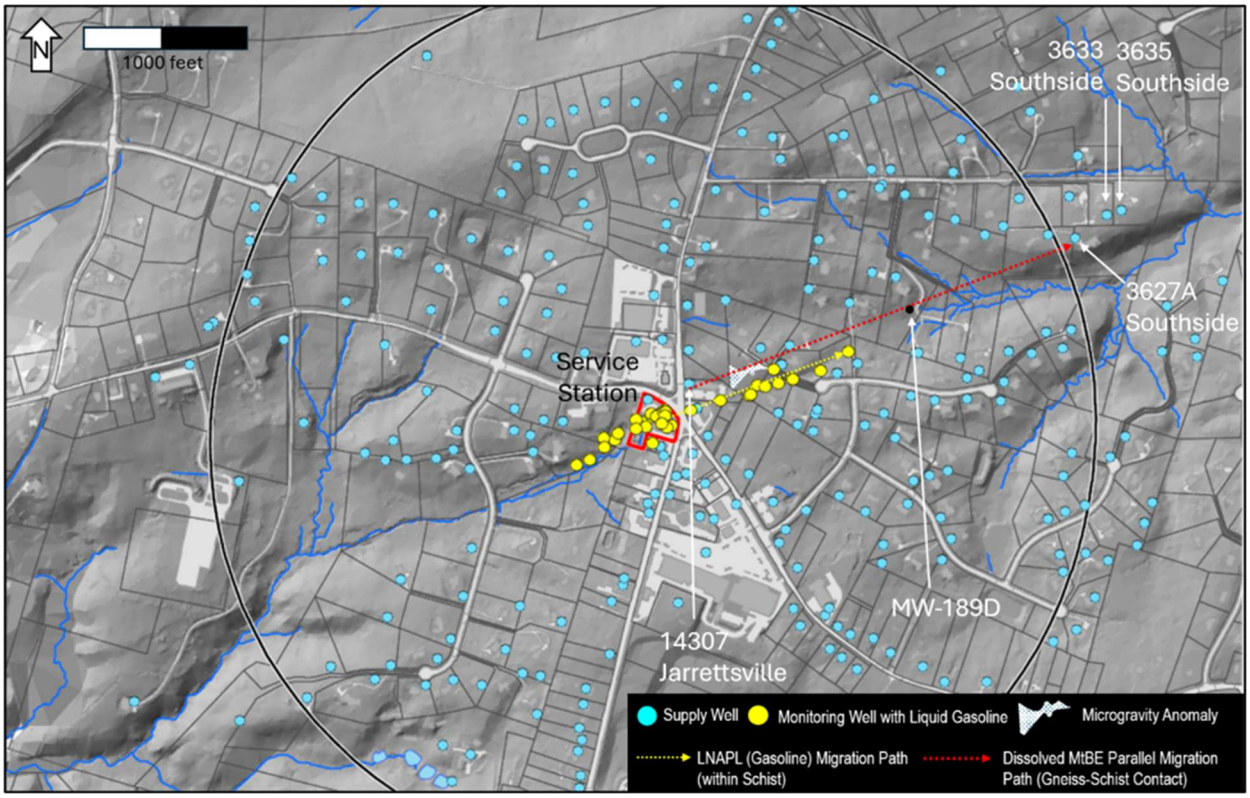
4.2.8 Hydraulic Response to Groundwater Extraction



The following table summarizes the greatest distance at which drawdown was measured relative to the structural orientation of the bedrock foliation:

© 2026 Kleinfelder

PUMPING WELL	OBSERVATION WELL	DISTANCE (FEET)	DRAWDOWN (FEET)	STRUCTURAL ORIENTATION
MW-77B	MW-61A	185	0.07	Up dip
	MW-81	223	0.09	Along Strike (Downgradient)
MW-112	MW-70	268	0.04	Up dip
	MW-113	122	0.08	Along Strike (Downgradient)

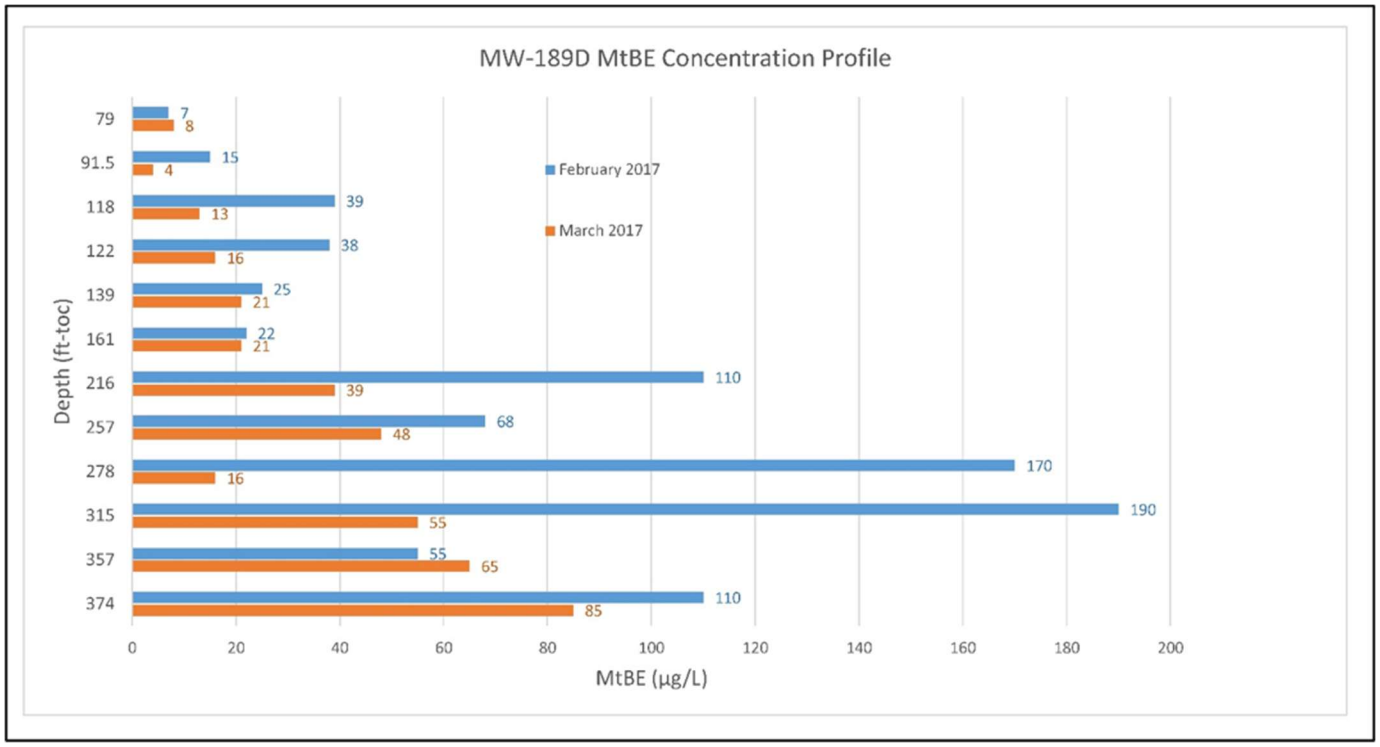


4.2.9 Migration to Distal Northeast

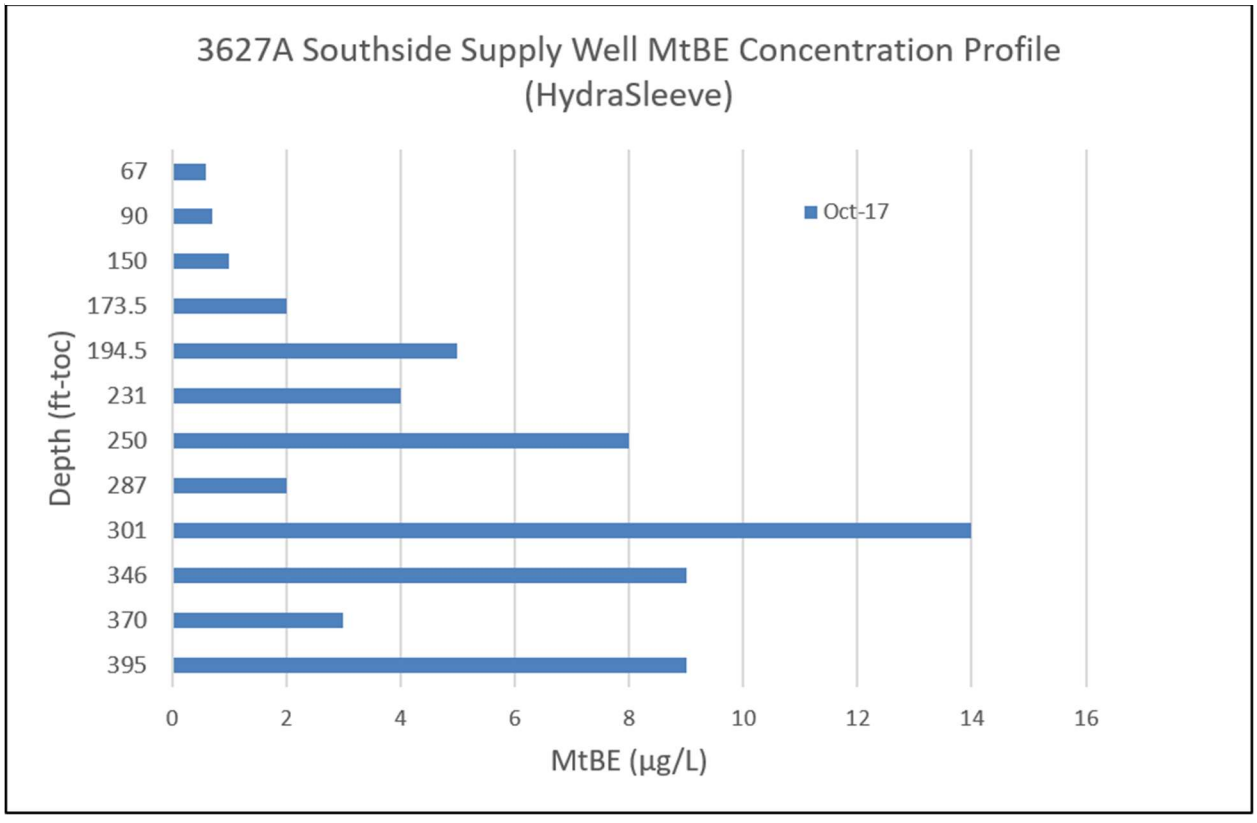
Increasing MTBE concentrations were identified in the distal northeast 3627A Southside Avenue private supply well leading up to the submission of the July 15, 2016 CSM Report (maximum concentration of 36 µg/L on October 6, 2015 prior to CSM submission). The azimuth from inactive Exxon service station to the 3627A Southside Avenue private supply well generally corresponds to the strike of metamorphic foliation in bedrock, and is also aligned with the previously demonstrated geophysical anomaly corresponding to a geologic contact between gneiss and schist (Graphics 7 and 8).

Graphic 7: Geologic map of site area with lithologic contact and foliation influencing flow

© 2026 Kleinfelder



Graphic 8: Site area, station location, and migration pathways



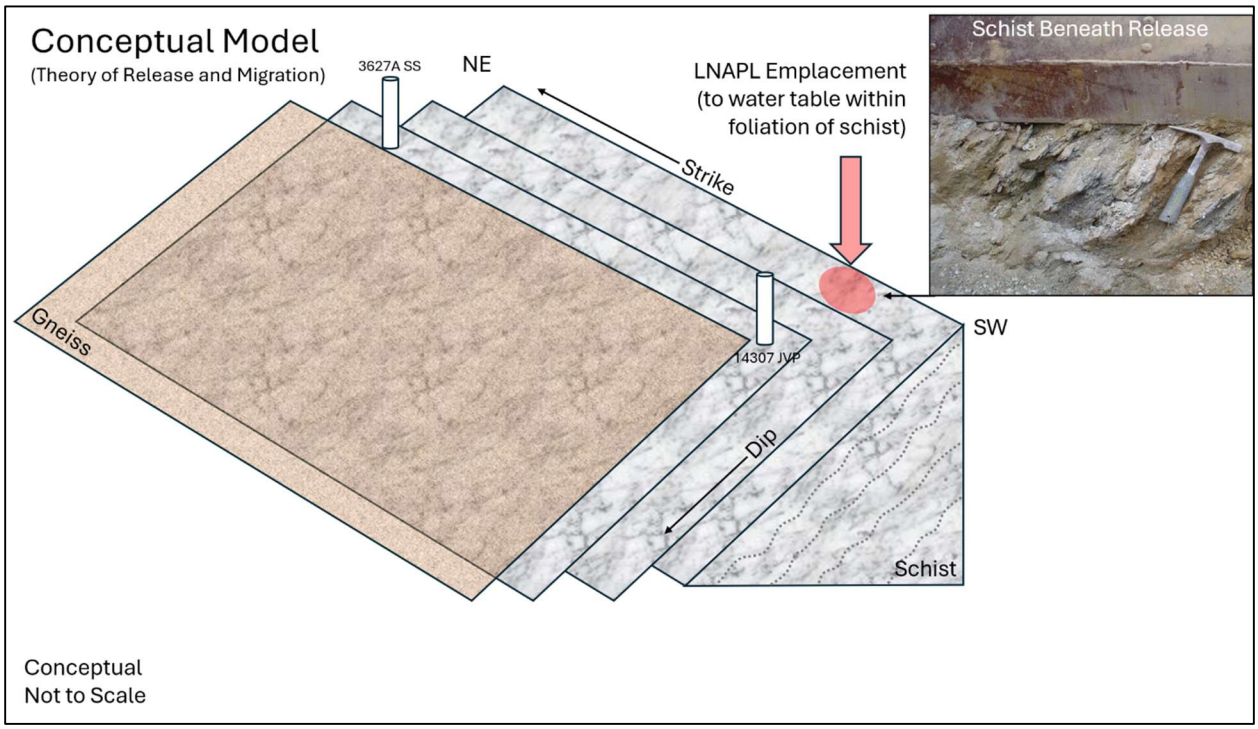
In December 2016, monitoring well MW-189D was installed on this alignment to investigate a potential migration pathway to the distal northeast (Graphic 8). Sampling of MW-189D confirmed the presence of MTBE. Private supply wells located at 3633 and 3635 Southside Avenue are located farther to the northeast from 3627A Southside Avenue (Graphic 8). MTBE has been consistently non-detect in the 3633 Southside Avenue supply well, which is located slightly off-strike from the suspected line of migration. The maximum MTBE concentration measured in the 3635 Southside Avenue supply well was 7.8 µg/L on December 4, 2023.

Graphics 9 and 10 illustrate the vertical concentration profile for MW-189D and 3627A Southside Avenue sampled via HydraSleeve™ in 2017.

© 2026 Kleinfelder

Graphic 9: Vertical concentration profile of MW-189D measured in 2017 via HydraSleeve™

Graphic 10: Vertical concentration profile of 3627A Southside Avenue measured in 2017 via HydraSleeve™

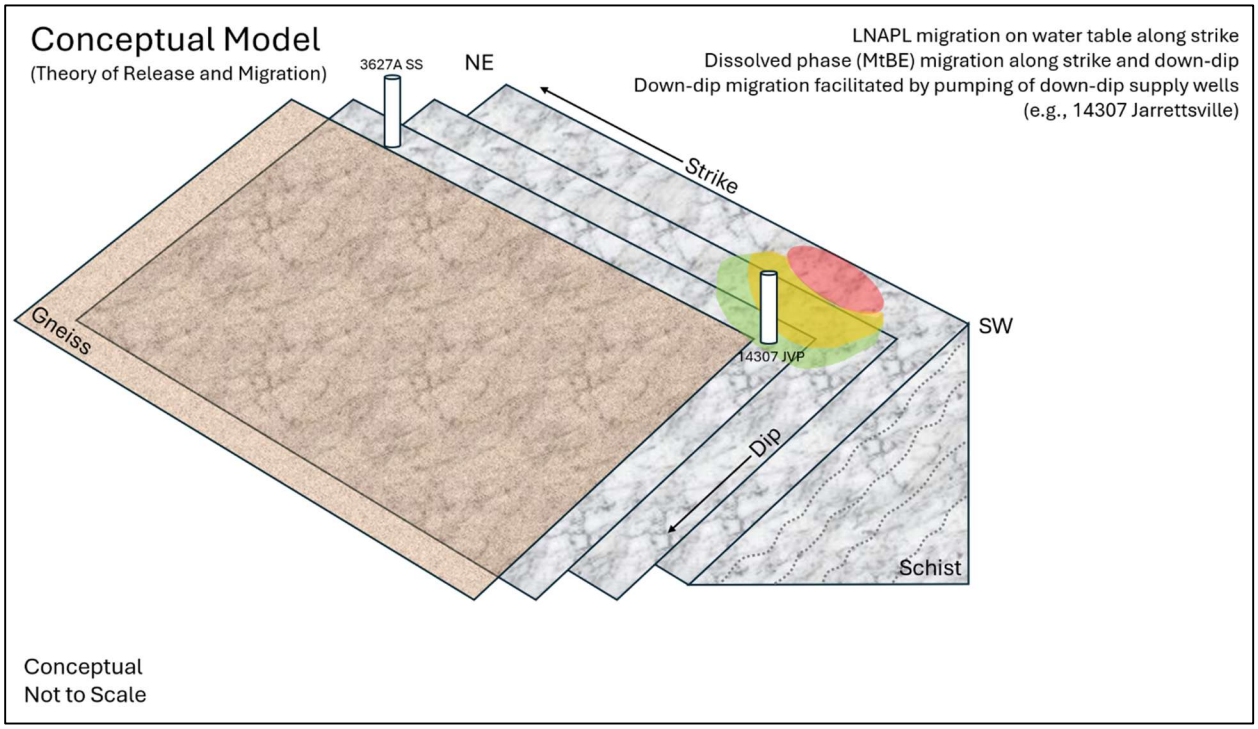


© 2026 Kleinfelder

Comparison of Graphics 9 and 10 indicates similar concentration profile with depth and sufficient upgradient concentration in MW-189D to account for the downgradient concentrations in the 3627A Southside supply well.

4.2.9.1 Distal Northeast Release and Migration Conceptual Model

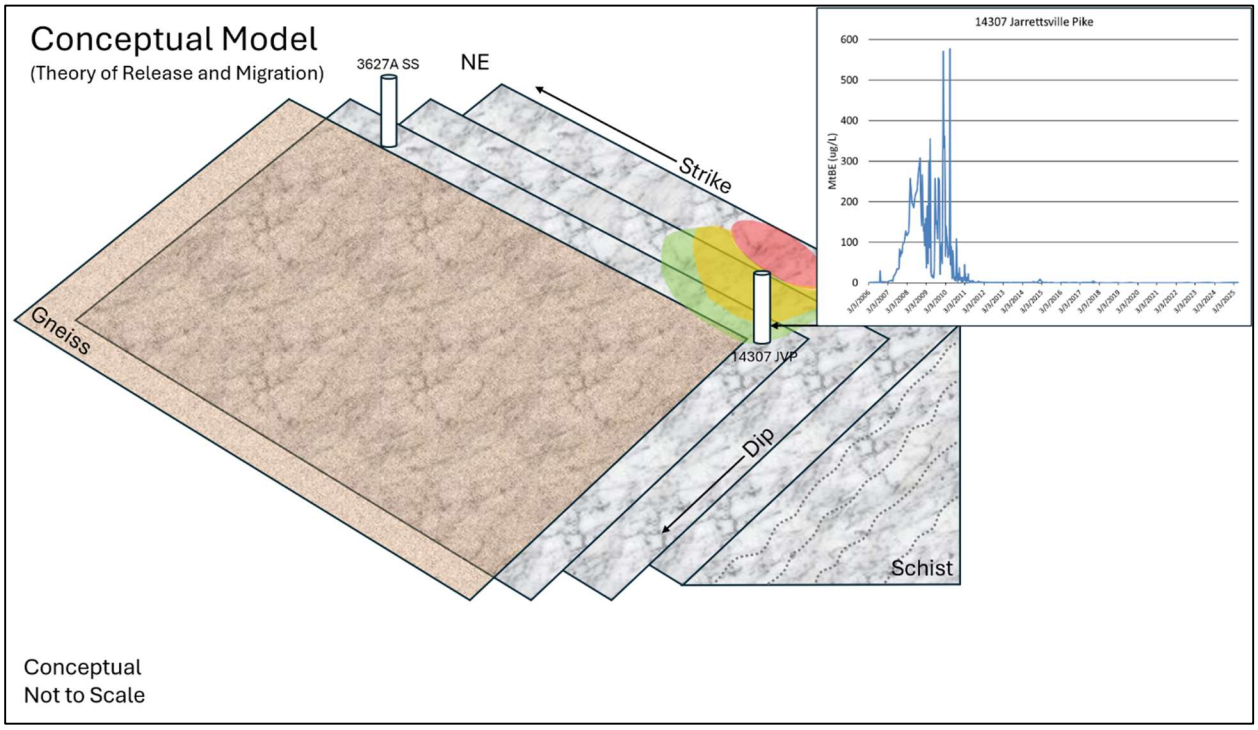
The release and migration conceptual model is illustrated in a series of graphics and is summarized, as follows:



1) Gasoline was released to the subsurface at inactive Exxon Station #28077, 14258 Jarrettsville Pike; head pressure caused vertical penetration of the foliation of the metamorphic bedrock (schist) (Graphic 11).

Graphic 11: Distal northeast release and migration conceptual model – LPH emplacement

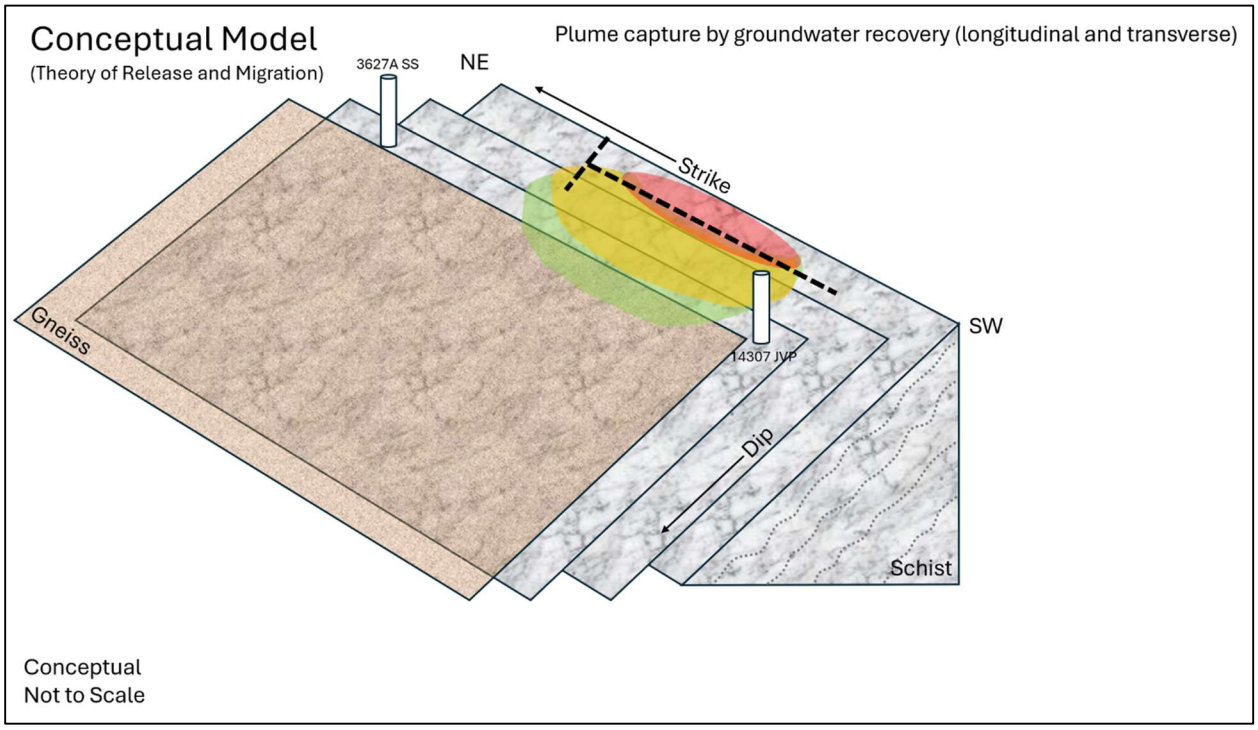
Gasoline encountered the water table in the bedrock and migrated laterally northeast (and southwest) on the water table along the foliation of schist in accordance with the hydrogeologic condition of anisotropy (Graphic 12).



© 2026 Kleinfelder

Graphic 12: Distal northeast release and migration conceptual model – LPH migration

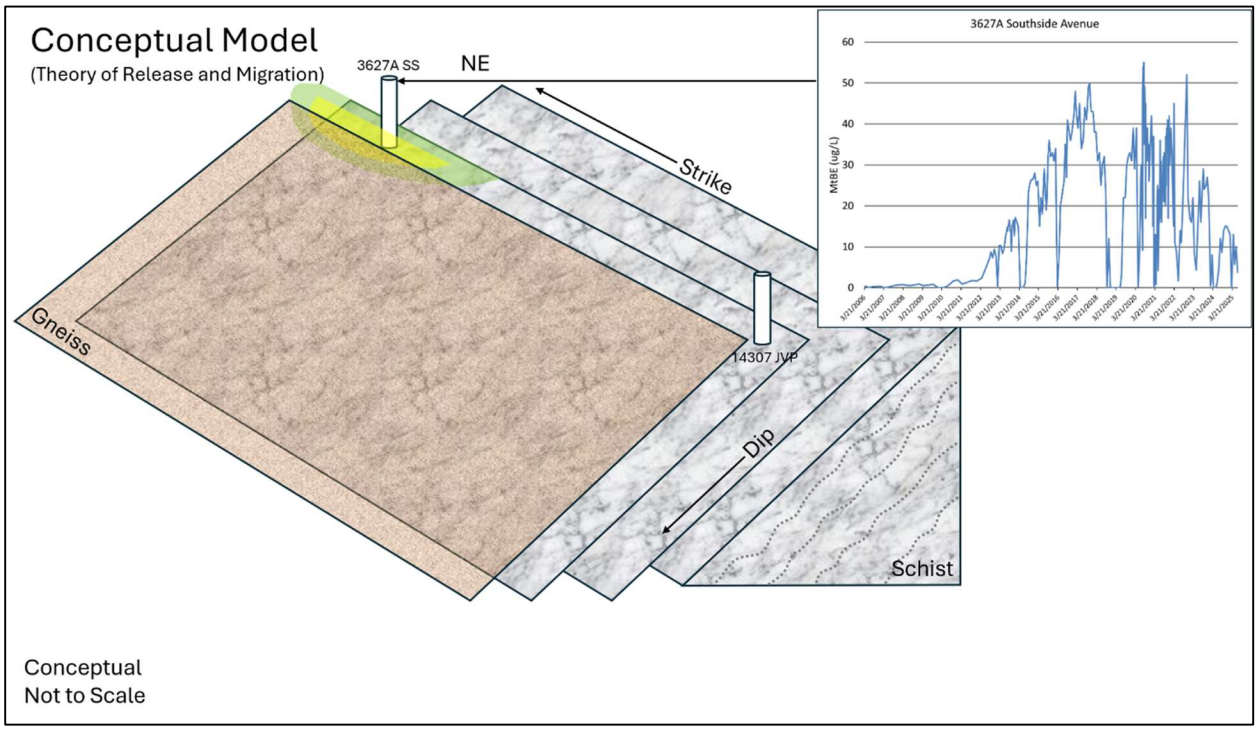
2) Dissolved phase MTBE was entrained by the pumping of the 14307 Jarrettsville Pike supply well, migrating downdip to that location from the occurrence of gasoline on the water table, resulting in a pulse of MTBE passing through this well (Graphic 13).



© 2026 Kleinfelder

Graphic 13: Distal northeast release and migration conceptual model – pulse passing through 14307 Jarrettsville Pike

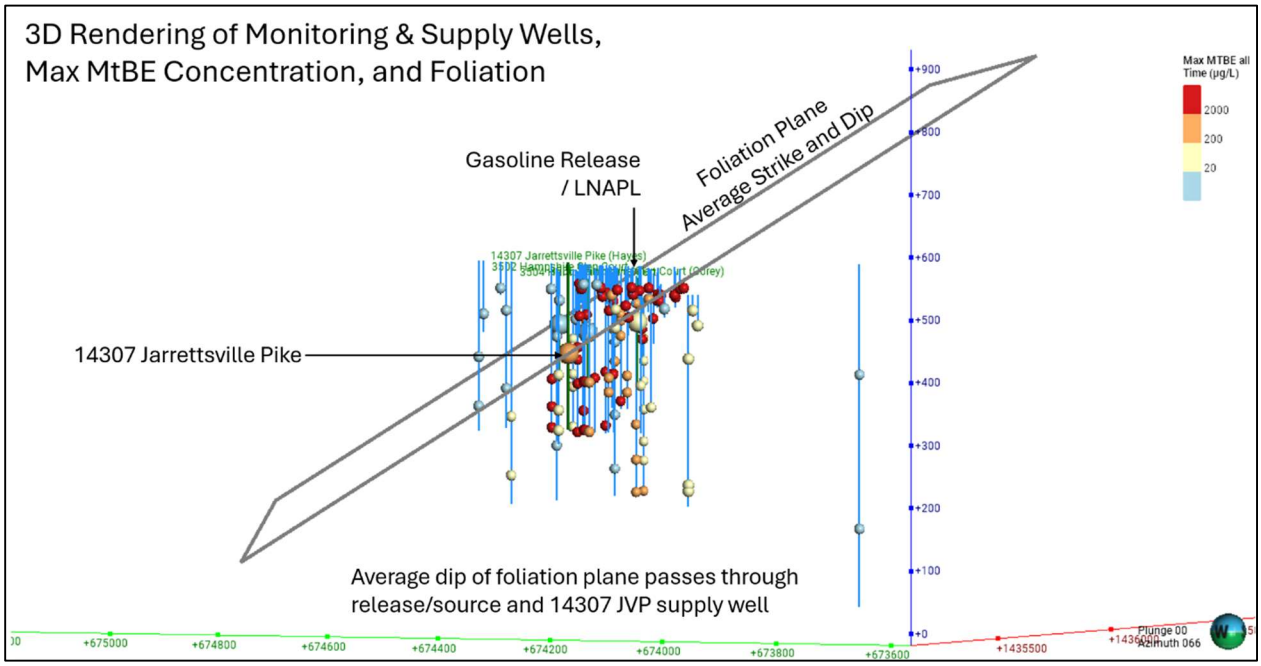
3) The pulse of MTBE migrated northeast along the strike of the metamorphic foliation and parallel to the northeast linear migration of LPH (Graphic 14). The northeast migration of MTBE is potentially coincident with the contact between two metamorphic bedrock types (gneiss and schist) where a parting (secondary porosity feature) is suspected (Graphic 14). The up-dip portion of the plume was captured by the groundwater recovery system (Graphic 14).



© 2026 Kleinfelder

Graphic 14: Distal northeast release and migration conceptual model – plume capture

4) The downdip fringe of the MTBE pulse migrated to the 3627A Southside Avenue supply well, which is located on the line of strike from 14307 Jarrettsville Pike. The MTBE experienced dispersion along this migration pathway, resulting in decreased concentration with mass spread longitudinally along strike over time and distance (Graphic 15). This pulse also reached the 3635 Southside Avenue supply well at a maximum concentration less than the state action level of 20 µg/L.

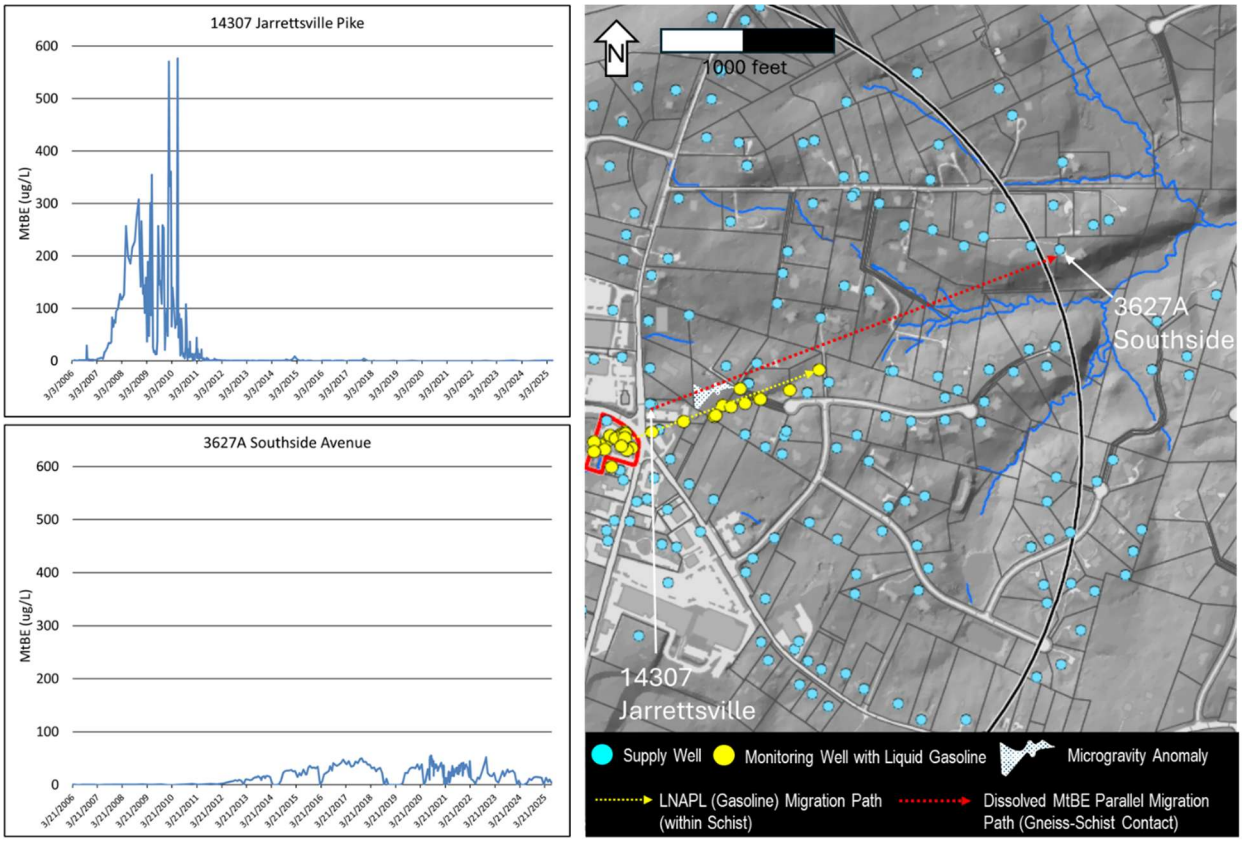


© 2026 Kleinfelder

Graphic 15: Distal northeast release and migration conceptual model – MTBE pulse passing through 3627A Southside

The downdip entrainment and migration of MTBE to the 14307 Jarrettsville Pike supply well is illustrated by the following scaled 3D model of actual depths of supply wells, monitoring wells, and sample intervals for maximum all-time MTBE concentrations (Graphic 16).

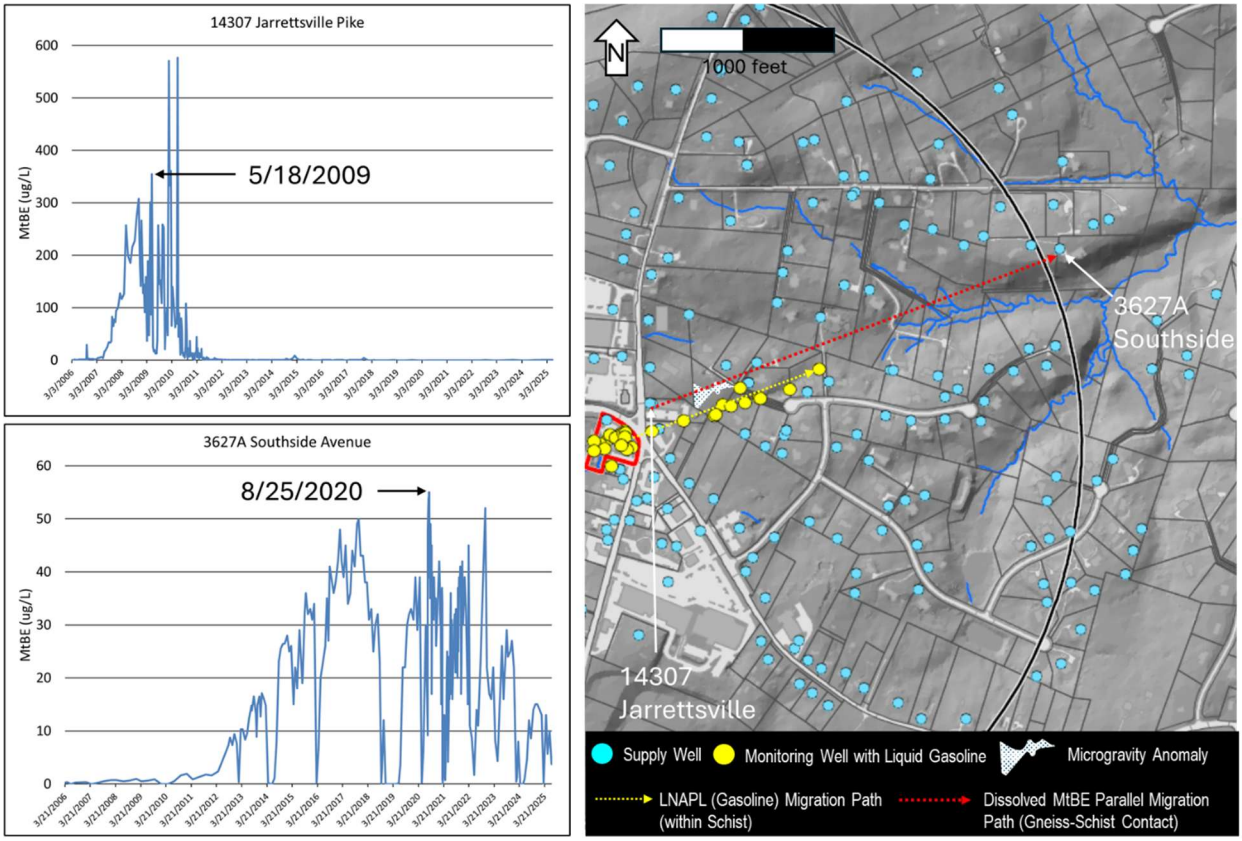
© 2026 Kleinfelder



Graphic 16: Downdip entrainment from gasoline release area to 14307 Jarrettsville Pike supply well

4.2.9.2 Distal Northeast Fate and Transport Analysis

Early knowledge of the release, rapid action to monitor supply wells, and a historic record of periodic and frequent sampling allow for an empirical fate and transport analysis based on the reconstruction of MTBE migration, which effectively served as a tracer of groundwater flow. The migration of MTBE occurred as a pulse that experienced advection and increasing dispersion over time and distance.



© 2026 Kleinfelder

Graphics 17 and 18 illustrate the arrival of the MTBE pulse at 14307 Jarrettsville Pike soon after the release, and its subsequent migration to and through the 3627A Southside Avenue location.

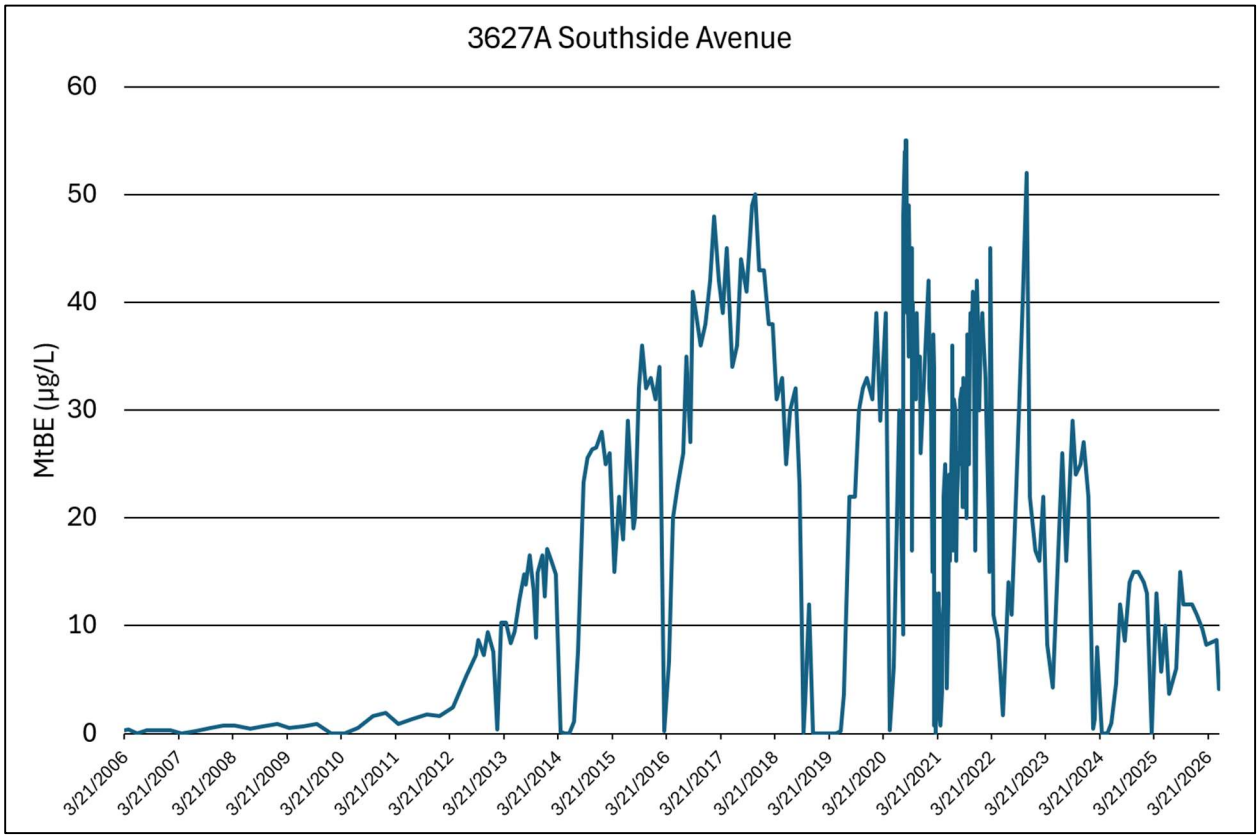
Graphic 19: MTBE concentration pulse through 3635 Southside

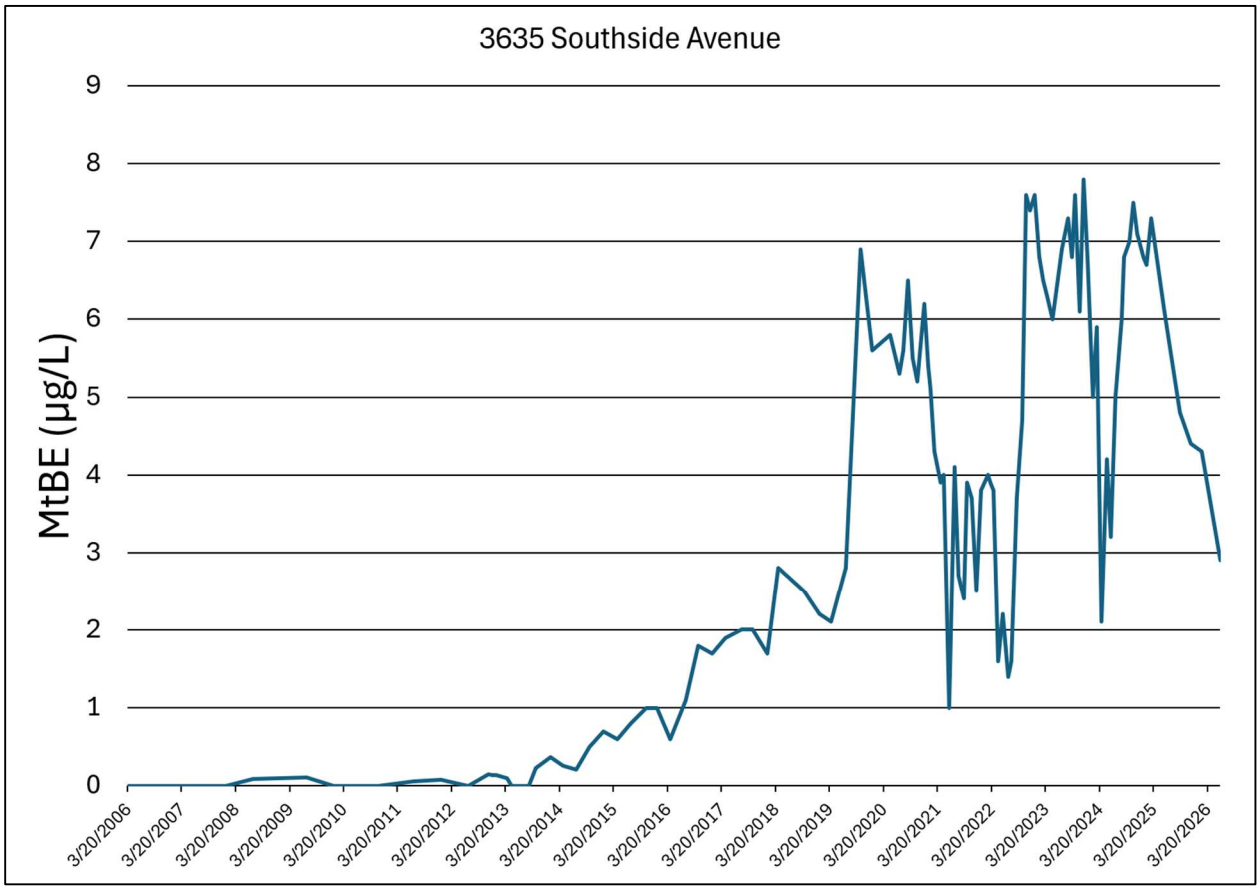
Graphic 20 shows the MTBE pulse for each private supply well superimposed on the same time and concentration scales.

© 2026 Kleinfelder



Graphic 20: Superimposed MTBE concentration trends 14307 Jarrettsville, 3627A Southside, 3635 Southside

4.2.9.3 Attenuation of Distal Northeast MTBE Pulse



Extensive periodic groundwater monitoring has been conducted on the distal northeast supply wells at 3627A and 3635 Southside Avenue since the July 15, 2026 CSM Report. It is evident from inspection of concentration trends that a pulse of MTBE migrated to the distal northeast which attenuated to below the State action level of 20 µg/L prior to reaching 3635 Southside Avenue (Graphics 21 and 22). This pulse will continue to dissipate at concentrations less than the State action level. The fate of the MTBE migration to the northeast has occurred; it is not expected to migrate any farther above the State action level.

© 2026 Kleinfelder

Graphic 22: MTBE concentration over time (2006 to 2026) for 3635 Southside Avenue

4.3 CONTAMINANT PHASES AND AFFECTED MEDIA

LPH, in the form of unleaded gasoline, and hydrocarbon constituents of gasoline dissolved in groundwater within the fractured bedrock aquifer represent the principal contaminant phases and affected media. A table of all historic groundwater gauging data, including LPH measurements, is presented in Appendix E. These phases have also occurred in groundwater within saturated overburden at distal / downgradient areas to the northeast and southwest where the water table occurs in the overburden above bedrock. A table of all historic groundwater analytical data is presented in Appendix F. The former tank field, where the gasoline release occurred, was excavated to the top of bedrock where the gasoline directly infiltrated the bedrock vertically via the inclined foliation of the schist bedrock. Groundwater occurs within bedrock (water table beneath top of bedrock surface) at this location. Consequently, the main gasoline release did not directly affect the soil medium and limited soil sampling was conducted, including during the installation of monitoring wells MW-5, MW-6, and MW-7, and during UST system removal activities.

© 2026 Kleinfelder

As reported in the July 2006 Preliminary Hydrogeologic and Contaminant Assessment Report (Kleinfelder, 2006a), all gasoline-related VOCs were either not detected at or above the laboratory reporting limit or were detected at concentrations below the MDE Soil Protection of Groundwater Standards in the monitoring well soil samples. As reported in the April 2006 Tank Excavation and Assessment Report (GSC/Kleinfelder, 2006b), soil samples were collected during UST system removal activities, including from the UST excavation sidewalls and bottom, and beneath dispensers and product and vent piping during decommissioning activities conducted from March 4 through April 10, 2006. Soil samples indicated exceedances of Maryland Soil Protection of Groundwater Standards for benzene, toluene, ethylbenzene, total xylenes, MTBE, Naphthalene, TPH GRO, TPH DRO and acetone in at least one sample. The UST excavation was completed to the top of bedrock and the sidewalls were shored, limiting the excavation extent to approximately 60 feet long by 46 feet wide and 14 feet deep. Soils beneath piping samples exhibiting VOC exceedances were over excavated on April 13 and 14, 2006 and post-excavation soil sample results were non-detect or below Maryland Soil Standards, with the exception of naphthalene and TPH-DRO at one location. A table of soil analytical data is presented in Appendix G.

4.4 SOURCE, PATHWAYS, POTENTIAL RECEPTORS

The former UST field where the gasoline release occurred and entered bedrock is the release area. The extent of gasoline LPH that migrated within bedrock on top of the water table along the strike of the foliation to the northeast and the southwest was a source of dissolved-phase gasoline constituents in groundwater. The maximum extent of LPH (~1,870 feet) is illustrated on Graphic 8.

LPH has been removed via the groundwater remediation system through total fluids pumping, multi-phase vacuum extraction, and soil vapor extraction. LPH has not been detected in any monitoring or recovery wells since 2008. Natural attenuation of gasoline constituents is supported by multiple lines of evidence as presented in the 2019 and 2022 MNA assessments. Migration of dissolved-phase gasoline constituents in groundwater has occurred via advection along strike within the foliation of the saturated bedrock to the northeast and southwest, and the extent of dissolved phase migration has been confirmed with the extensive monitoring well network and sampling program, including the installation of MW-189D and analysis of dissolved phase concentrations in monitoring and private supply wells in the NE distal extent. The extent of dissolved phase concentrations above MDE action levels has contracted and reduced both in areas where active remediation was implemented and beyond. Decreasing concentration trends continue in the post-remediation phase providing another line of evidence that natural attenuation is acting on remaining dissolved phase constituents, arresting potential migration by advection and stabilizing the plume.

© 2026 Kleinfelder

Area supply wells and streams to the northeast (tributary to the Sawmill Branch of Little Gunpowder Falls) and southwest (tributary to the Green Branch of Gunpowder Falls) represent potential receptors for the groundwater advection pathway. These receptors have been protected through implementation of remedial measures (mass removal and containment through groundwater extraction), monitoring, and deployment of POET systems where necessary. Dissolved phase COC concentrations in area PSWs have been below MDE standards for over two years, and surface water samples collected for 18 years never had a COC detection above standard.

Based on over 20 years of groundwater analytical data, including two and a half years of post-remediation monitoring, the areas with remaining dissolved phase concentrations of concern and potentially complete pathways toward nearby potential receptors are well defined as detailed below.

Intersection Area:

The intersection of MD Routes 145 and 146 is directly downgradient of the UST release area to the northeast and was the last area subject to active remediation when MW-187A, B and C were installed and connected to the remediation system following intersection reconstruction by State Highway Administration. Monitoring wells MW-187A and MW-187B within the intersection and monitoring wells MW-54 and MW-54B just northeast of the intersection along the western side of 14307 Jarrettsville Pike have exhibited rebound in concentrations of MTBE and benzene above established trigger levels during the post-remediation phase and typically exhibit the highest concentrations remaining across the project area (maximum MTBE and benzene concentrations in the second quarter of 2026 were 250 µg/L at MW-54B, and 340 µg/L at MW-187A, respectively), though concentrations at the deeper MW-187C and MW-54C remain below the trigger levels. As detailed in the prior section, there is an assumed pathway for down-dip migration from the former source area in the intersection area towards the 14307 PSW, and MTBE concentrations at the supply well previously exceeded 800 µg/L, though concentrations at this PSW have been below MDE standards for over 15 years. Therefore, continued monitoring of these intersection area wells (MW-187 and MW-54 cluster) and the 14307 Jarrettsville Pike PSW are warranted until concentrations are below MDE standards, or decreasing trends persist.

Distal NE Extent (Southside Neighborhood):

As detailed in the prior section, dissolved phase concentrations at MW-189D confirmed that MTBE detected in PSWs located at 3627A and 3635 Southside Avenue are likely from the same source, which originated by the downdip migration of hydrocarbon due to PSW pumping at 14307 Jarrettsville Pike, resulting in dissolved phase MTBE migration to the northeast. Concentrations at 3627A Southside have been below MDE standards for two years, and have never been above standard at 3635 Southside

© 2026 Kleinfelder

Avenue, and the concentration peak at each of these wells appears to have passed and will continue to diminish in concentration that is already below standard. Additional monitoring of MW-189D and the PSWs at 3627A and 3635 Southside Avenue is warranted to confirm that concentrations at each location continue to decrease.

Hampshire Glen Neighborhood:

Between the intersection area and the distal NE extent, dissolved phase migration occurred down-dip (to the north), deeper and offset from the original pathway of LPH migration. This was extensively studied, particularly with investigations at 3501 Hampshire Glen Court and nearby properties following detection of increased MTBE concentrations in the PSW samples from 3506 Hampshire Glen Court, as detailed in the 2016 CSM. Concentrations at the 3506 Hampshire Glen Court PSW, and all PSWs in the Hampshire Glen neighborhood have been below MDE drinking water standards for over 17 years, and dissolved phase COC concentrations at most monitoring wells in the neighborhood are below standard or have decreasing trends. Trends at three monitoring wells (MW-47C, MW-82B, and MW82D) above MDE action levels and along the assumed offset pathway of deeper dissolved phase MTBE migration warrant continued monitoring along with the 3506 Hampshire Glen Court PSW, to maintain protection of this PSW where migration of dissolved phase MTBE previously occurred then abated following additional targeted upgradient remediation.

4.5 RESPONSE TO REMEDIATION AND REMEDIAL EFFECTIVENESS

The combination of total fluids pumping, multi-phase vacuum extraction, and soil vapor extraction were effective at removing LPH and dissolved-phase mass while containing and contracting the extent of dissolved-phase hydrocarbons in groundwater, and remaining localized residual concentrations represent insufficient mass for plume expansion while also being subject to natural attenuation processes.

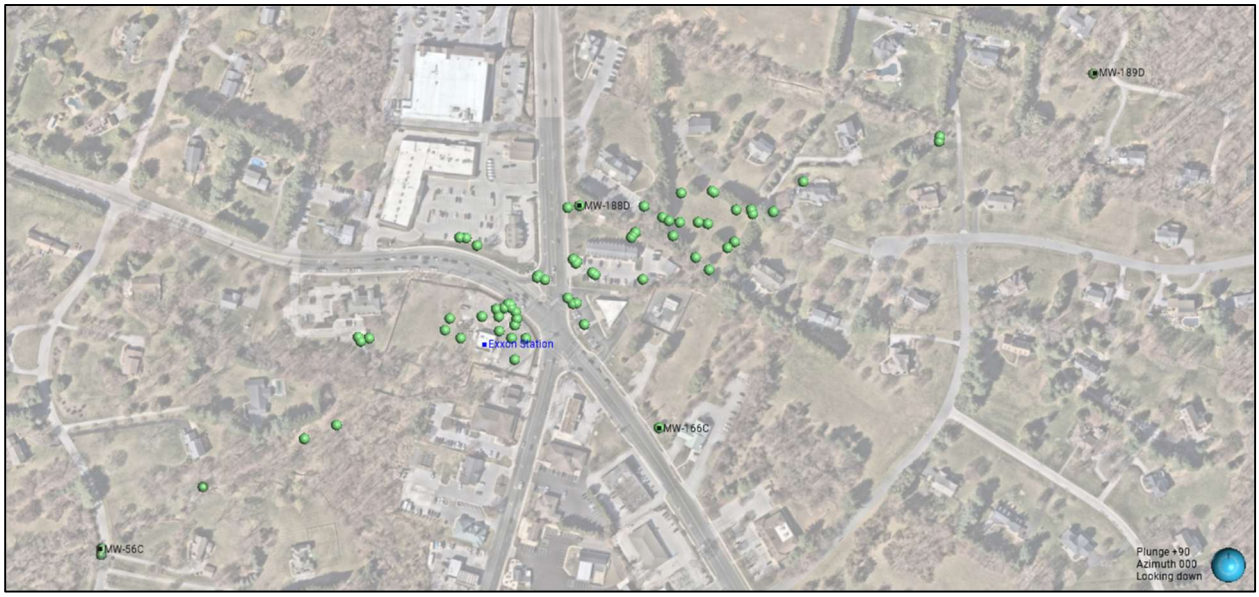

Figure 8 illustrates the historical maximum extent of LPH migration. The maximum extent of LPH was 1,870 feet from southwest to northeast along the strike of the bedrock foliation. LPH has not been detected in any monitoring or recovery well since 2008.

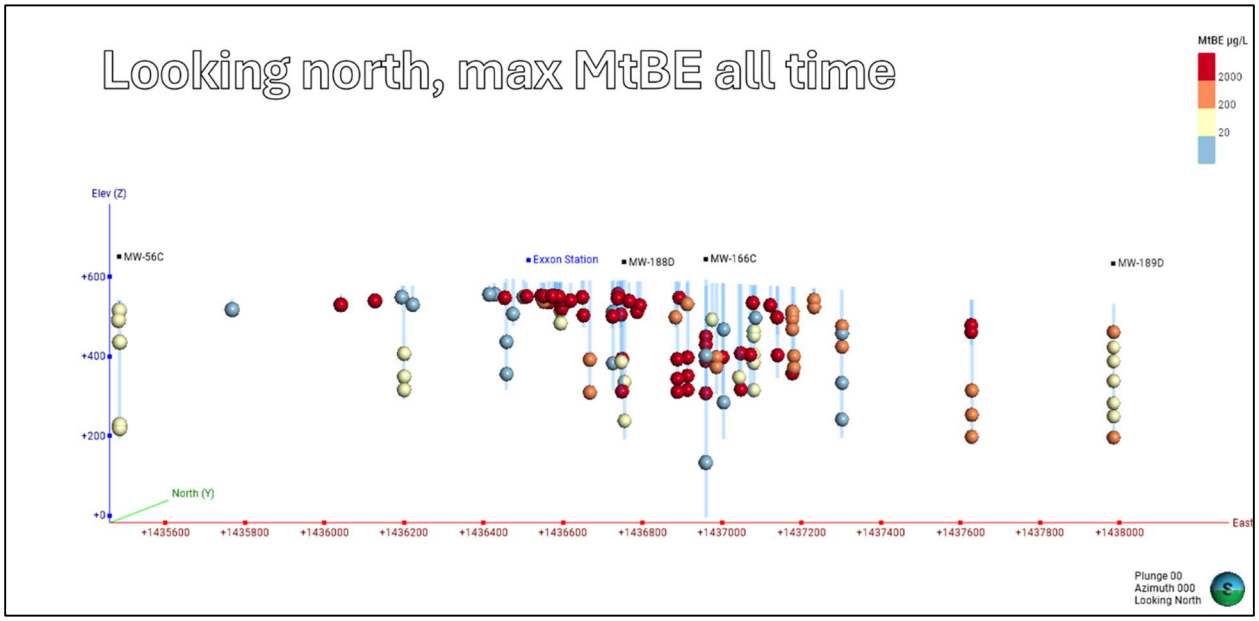
4.5.1 3D Visualization of MTBE Reduction

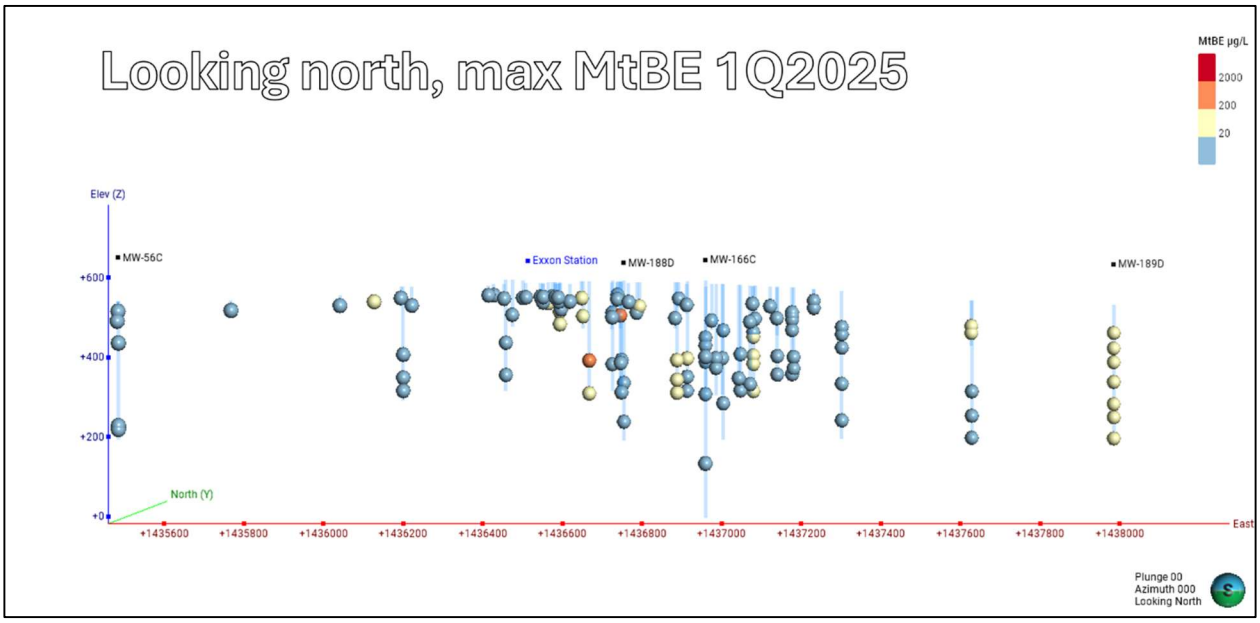
A 3-dimentional visualization of the monitoring well network, including discrete interval MTBE concentrations (maximum all time and maximum in 1Q2025) was provided to MDE in the *Discrete Depth Sampling Results, Sampling Modification, and Well Abandonment Work Plan* (Kleinfelder, 2025). This



© 2026 Kleinfelder

information is excerpted and presented herein. This data presentation provides for direct visual comparison of the MTBE concentration reductions from the maximum results measured at any time during the project, representing a clear visual indicator of remedial effectiveness in 3D. Monitoring wells included in the 3D visualization are presented in Graphic 23.

Graphic 23: Monitoring well locations used in 3D visualization of MTBE distribution



All-time maximum MTBE concentrations are presented in Graphic 24, looking north.

Maximum MTBE concentrations measured in the First Quarter 2025 are presented in Graphic 27, looking northeast along bedrock strike.

Graphic 27: Maximum MTBE concentration in 1Q2025 looking northeast

Early in the project, MTBE concentrations above the action level of 20 µg/L were widespread throughout the monitoring well network; most monitoring wells and discrete depths exceeded the action level at some time (with most exceeding 200 µg/L MTBE). Some locations never had MTBE concentrations exceeding the action level, including MW-50 and MW-50B west of the former station, the MW-146 cluster north of the station, unused supply wells PW-14311 and PW-3501 northeast of the station and the unused supply well MW-166 to the east of the station.

By contrast, in the first quarter 2025 most monitoring wells and discrete depth intervals were below the MTBE action level. The locations of remaining MTBE concentrations above 20 µg/L were concentrated around the former UST field and within and immediately east of the intersection of State Highway Routes 145 and 146, and interspersed to the northeast at a handful of locations with recalcitrant concentrations between 20 to 200 µg/L.

The 3D visualization demonstrates the marked reduction in MTBE concentrations within the monitoring well network both in space and in magnitude of concentration reduction.

© 2026 Kleinfelder

4.5.2 Recovery Well Conversions

Due to the effectiveness of the remediation systems in removing recoverable hydrocarbon mass, recovery wells were approved for shutdown in a gradual and sequential manner to allow for monitoring of effects. Since the 2016 CSM Report through final system shutdown in December 2023, 63 recovery wells were shut down and converted to monitoring wells. On the few occasions where rebound in concentrations was observed following recovery well conversions it was typically low level and short-lived, indicating that groundwater concentration trends were influenced less by groundwater pumping than natural attenuation in areas where most of the recoverable mass was depleted.

4.5.3 Natural Attenuation

On July 25, 2019, Kleinfelder, on behalf of ExxonMobil, submitted a *Natural Attenuation Evaluation Report* (Kleinfelder, 2019) to MDE. The potential for microbial biodegradation in shallow and deep portions of the aquifer is indicated based on the following observations and conditions:

- There is an abundance of MTBE and BTEX degraders present throughout the aquifer, especially aerobic degraders.
- Microbial environmental conditions (temperature and pH) are within the optimal range for microbial activity, and the microbial nutrient, orthophosphate, is available.
- Stable Isotope Probing indicates:
    - MTBE was incorporated into microbial biomass and metabolized in the MW-27B sample, but not in the MW-40 and MW-189D sample. Mineralization was not evident during the period of deployment.
    - Benzene was incorporated into microbial biomass and metabolized in the MW-54C sample though mineralization was not evident at this well during the period of deployment.
- Oxygen is available for aerobic biodegradation:
    - Positive ORP conditions exist throughout much of the aquifer
    - The shallow zone is replenished with oxygenated water through recharge and water table fluctuation.

A discrete area of negative ORP was measured in the deep portion of the aquifer beneath 3501 Hampshire Glen Court, which corresponds to residual concentrations of gasoline constituents that were sequestered at depth. Additionally, this zone did not experience as much remediation influence nor substantial

© 2026 Kleinfelder

replenishment of oxygenated water via recharge. This pattern is evidence of active biodegradation occurring at a remaining 'pocket' of sequestered and recalcitrant gasoline constituents in the aquifer. Downgradient migration of gasoline constituents, particularly MTBE from this area would enter an aerobic portion of the aquifer with the dissolved oxygen capacity and aerobic MTBE degraders necessary to degrade and mineralize MTBE, limiting migration. In 2022 a second round of natural attenuation data was collected while the system was offline for the cycling assessment, and as reported in the January 24, 2023 *Recovery Well Cycling Report of Results* (Kleinfelder 2023a) the data indicated the continued presence of geochemical indicators and of petroleum and oxygenate degraders which will continue to degrade remaining concentrations of MTBE and benzene.

4.5.4 Remediation System Shutdown

As reported in the July 31, 2023 *Phase 2 Recovery Well Cycling Report of Results and Request for Post-Operational Monitoring* (Kleinfelder 2023b), with most of the recoverable hydrocarbon mass already removed, groundwater recovery and hydrocarbon mass recovery rates at the end of remediation system operations were significantly diminished. During the Phase 2 cycling assessment in February and April 2023, the groundwater recovery rate from the remaining four wells, MW-38C, MW-54B, MW-187A and MW-187C, averaged 0.2 gallons per minute (288 gallons per day). With system influent concentrations below MDE standards at the conclusion and following the Phase 2 cycling assessment, the dissolved phase mass recovery rate in June 2023 for BTEX and MTBE was 0.00004 lbs/day, or 0.015 lbs/year. Groundwater concentrations throughout the monitoring well network maintained consistent trends and the footprint of remaining impacts remained stable with no indication of migration of impacts during the cycling assessments. Therefore, due to the negligible apparent benefit of continued system operation, plume stability, and evidence of natural attenuation, system shutdown and post-remediation monitoring was recommended and approved by the MDE in its December 19, 2023 letter (MDE 2023).

4.5.5 Post-Remediation Groundwater Conditions

Ten quarters of post-remediation groundwater sampling at 51 monitoring wells have been conducted, including quarterly and semi-annual sampling. Additional monthly sampling has been completed at monitoring wells where groundwater concentrations have been detected above trigger levels that were established for MTBE and benzene in the MDE's *December 19, 2023 Post-Remediation Monitoring Approval Letter* (MDE, 2023). Additionally, 15 private supply wells are sampled at various frequencies, including one monthly, three quarterly, and 11 semi-annually.

© 2026 Kleinfelder

Monitoring Well Trends

Post-remediation monitoring well groundwater concentrations and trends have been evaluated relative to the MDE drinking water standards for MTBE and benzene, which are the two compounds with exceedances of the MDE standards within the monitoring well network. Of the 51 remaining monitoring wells, 25 have had at least one MTBE or benzene detection above standard in the 2.5 years of post-remediation monitoring, while 26 monitoring wells have remained below standards since system shutdown. For wells with at least one exceedance, additional trend analysis has been conducted. Of the 25 monitoring wells that have had at least one dissolved phase constituent (MTBE or benzene) detection above standard since system shutdown, 13 exhibit trends generally consistent with pre-shutdown trends and have not exceeded a trigger level, and 12 wells showed some level of rebound in concentrations compared to when the system was operating, including eight wells that have had at least one trigger value exceedance for MTBE or benzene. The different post-remediation monitoring well trends and the wells which fall into each behavior are detailed below.

Concentration trends have been evaluated for the 25 monitoring wells which have had at least one exceedance of an MDE action level during the first 2.5 years of post-remediation monitoring. Concentration trend graphs have been prepared using GWSDAT for monitoring wells with at least one detection of MTBE or benzene above standard and for both the historic data set, as well as the first 10 quarters of post-remediation monitoring. For some monitoring wells, a third trend graph is included for the latest 8 quarters for comparison (Appendix H). First quarter 2026 monitoring well MTBE and benzene concentrations are shown on Figure 9e. Concentration trends are discussed below, the spatial distribution of concentration trends are presented on Figure 14, and trends at each monitoring well are summarized in Appendix I.

Monitoring Wells with Concentration Increase

Fifteen monitoring wells exhibited some level of rebound in concentrations leading to a negative half-life (potentially increasing trend) calculated in GWSDAT for the post-remediation period, however for several wells, trends were generally consistent with pre-shutdown trends when viewing the full history trend graph. Additionally, when reviewing the last 1 to 2 years of MTBE and/or benzene data, 11 of the 15 wells appear to have stable or fluctuating trends. This includes monitoring wells MW-6, MW-16R, MW-17, MW-27B, MW-40, MW-45, MW-73C, MW-82B, MW-181C, MW-187B, and SVE-1.

Four of the 15 wells currently have increasing trends considering both the 2.5-year post-remediation period, and the most recent data: MW-47C, MW-54, MW-54B, and MW-82D. The increasing trends at MW-47C and MW-82D appear to pre-date system shutdown. The increased concentrations in some

© 2026 Kleinfelder

monitoring wells following system shutdown is likely due to a new equilibrium being established as recovery well pumping ceased, reducing the entrainment of cleaner water into the areas under active pumping. Eleven out of the 15 wells are exhibiting stabilizing trends, and it is expected that with no ongoing source in the area, attenuation will in time lead to decreasing trends. It is expected that the four wells that continue to exhibit increasing trends post-remediation, similarly will stabilize with time and then begin to decrease, and monitoring should continue at these wells to confirm that decreasing trends are established, particularly at monitoring wells proximal to private supply wells.

Monitoring Wells with Stable to Decreasing Trends

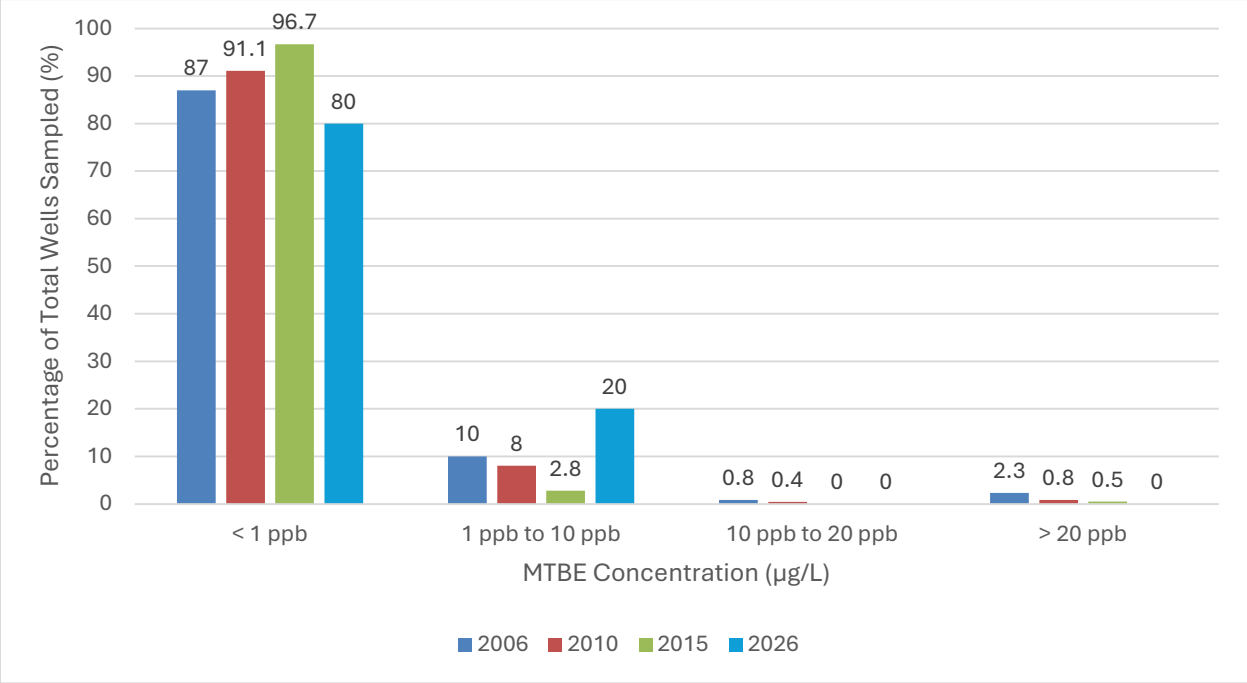
Ten monitoring wells exhibit stable to decreasing concentration trends for at least the last two years, although they have had at least one action level exceedance within the post-remediation monitoring period, including MW-38C, MW-45R, MW-54C, MW-139, MW-178C, MW-181A, MW-187A, MW-187C, MW-189D, and SVE-2. Generally, once stable trends have been confirmed for two years or more, continued monitoring is unnecessary. In some cases if wells are part of a cluster or proximal to wells with elevated, potentially increasing concentrations and a potential migration pathway, continued monitoring may be prudent.

Monitoring Wells Consistently Below Standards

Of the 51 monitoring wells sampled during the first ten quarters of post-remediation monitoring, concentrations in 26 monitoring wells have been below MDE action levels for the entirety of the post-remediation monitoring period to date: MW-1, MW-15, MW-22, MW-27R, MW-36R, MW-38, MW-48BB, MW-50C, MW-56C, MW-58, MW-72, MW-85, MW-91C, MW-138D, MW-146, MW-146B, MW-146C, MW-168, MW-176, MW-178B, MW-179C, MW-181B, MW-182, MW-184, and MW-188D. These include A, B, C, and D wells distributed throughout the project area, including from the inactive station property, along the path of product migration, and beyond. Some wells previously contained LPH and were used for active remediation, some wells had prior dissolved phase exceedances of MDE standards, and other wells have never had detections above MDE standards. During post-remediation monitoring, of these 26 wells, the maximum MTBE detection was 10 µg/L in MW-179C in the third quarter of 2024, though all the other MTBE results have been either non-detect or detections less than one half of the MDE action level of 20 µg/L. During post-remediation monitoring, of these 26 wells, the maximum benzene detection was 1.2 µg/L in MW-184 in the third quarter of 2024, while all the other benzene results have been either non-detect or less than or equal to 1 µg/L, which is one-fifth of the MDE action level of 5 µg/L. The consistent results below MDE standards at these monitoring wells throughout the post-remediation period and prior,

© 2026 Kleinfelder

indicate there is de minimis risk related to gasoline impacts to groundwater at these locations because after over 20 years of remediation and monitoring, there is either no remaining source of concern, no migration pathway, or both, and continued monitoring is unnecessary.



Private Supply Well Trends

Fifteen PSWs are currently sampled at properties from Robcaste Road in the west to Southside Avenue in the east, as shown on Figure 15. As shown in time-series plots of PSW MTBE concentrations (Appendix J), all but one supply well have remained consistently below MDE drinking water standards, with no detections above one half of the MTBE drinking water standard of 20 µg/L, and most results either non-detect or an estimated J-flag throughout the 2.5 years of post-remediation monitoring. In the MDE's September 19, 2025 letter, MDE required continued semi-annual sampling of the PSW at 3600 Hampshire Glen Court for at least one year due to an estimated benzene detection of 0.14 µg/L, though concentrations have never been detected above MDE standards at this PSW. The samples collected from this PSW in third quarter 2025 and first quarter 2026 were non-detect for all constituents, including benzene.

Since system shutdown, the PSW at 3627A Southside Avenue has had one MTBE detection above the MDE standard in January 2024, and each monthly sample result since February 2024 has been below the MDE standards, and as discussed previously, MTBE concentrations at this location and 3635 Southside Avenue, which is the farthest PSW sampled to the northeast, are exhibiting decreasing trends. System shutdown has not adversely affected PSW concentrations, as all PSW concentrations have been below MDE standards for over 2.5 years, and decreasing trends are established. A table of historic PSW analytical data is presented in Appendix K.

© 2026 Kleinfelder

Private Supply Well MTBE Concentration Reduction Over Time

Graphic 28: MTBE concentration reduction over time in private supply wells

Spatial Distribution of Trends

The spatial distribution of groundwater MTBE and benzene trends in monitoring and private supply wells is shown on Figure 14 and discussed by site areas below.

Inactive Station and West / Southwest of Intersection

West of the intersection of MD Routes 145 and 146, 18 monitoring wells remain on 14258 Jarrettsville Pike (inactive station), 3320 Papermill Road, 3313 Papermill Road, 14223 Robcaste Road, and in Robcaste Road. Ten of these wells have been consistently below standards throughout post-remediation monitoring and earlier, including in some wells that have never had a single detection above MDE standards: MW-1, MW-15, MW-22, MW-27R, MW-50C, MW-56C, MW-72, MW-146, MW-146B, and MW-146C. The other 8 wells, MW-6, MW-16R, MW-17, MW-27B, MW-40, MW-139, SVE-1, and SVE-2, have had at least one detection above standard since system shutdown, though recent trends are stable or decreasing.

© 2026 Kleinfelder

The maximum post-remediation MTBE concentration in wells west of the intersection was 68 µg/L at MW-27B in the third quarter of 2025; there have been no exceedances of the established MTBE trigger levels. One well west of the intersection, MW-40, has exceeded the benzene trigger level of 25 µg/L since system shutdown, with a maximum benzene concentration of 140 µg/L in the first quarter of 2025; benzene concentrations during the last three sampling events in March, April and May 2026 are again below the trigger level. MW-40 has exhibited fluctuating concentrations for most of its 20-year sampling history, including during recovery well operation at MW-40 and surrounding wells. Dissolved phase composition at MW-40 includes relatively higher concentrations of BTEX compounds than MTBE when compared with other monitoring wells, and MW-40 is a shallow well screened from 5 to 30 feet below top of casing and is located adjacent to a stream channel which receives stormwater runoff from commercial properties on Jarrettsville Pike. Concentrations measured at MW-40 are likely influenced by stormwater runoff and associated groundwater elevation fluctuations, representing a localized anomaly that has not contributed to elevated or fluctuating concentrations in other nearby wells. Excluding MW-40, the maximum post-remediation benzene concentration in wells west of the intersection was 22 µg/L at SVE-1 in the fourth quarter of 2025 and the first quarter 2026. With the exception of MW-40, there have been no exceedances of the established benzene trigger level west of the intersection.

There are currently 6 PSWs sampled to the west of the intersection and all of these wells have been below MDE drinking water standards for at least 14 years, including the 2.5 years of post-remediation monitoring, during which the maximum detected MTBE concentration was 3.6 µg/L at 3313 Papermill Road in February 2025.

Collectively, the groundwater conditions at the inactive station and other properties west of the intersection have significantly improved following approximately 18 years of active remediation as well as natural attenuation, supported by over 20 years of monitoring data, including 2.5 years of post-remediation monitoring. Most of the wells west of the intersection have remained consistently below standards throughout the post-remediation period. Of the wells that have had at least one detection above standard since system shutdown, concentrations have since subsided or stabilized at levels that do not indicate remaining source or migration pathways of concern. Based on the post-remediation and historic monitoring and private supply well concentrations and trends west of the intersection, there is no apparent complete exposure pathway between the source and a receptor exposure pathway between the source and a receptor which could lead to human or ecological exposure of unacceptable levels of gasoline-related constituents, therefore continued monitoring west of the intersection is no longer necessary.

© 2026 Kleinfelder

Intersection and Adjacent Properties East of Jarrettsville Pike

This portion of the site is where the highest concentrations remain, which as discussed previously, is expected since this area is immediately downgradient from the UST release area, and direct remediation within the intersection via the MW-187 well cluster was delayed until the intersection reconstruction project was completed by SHA in 2014. LPH migrated from the UST area, across the intersection to the east / northeast and was observed in monitoring wells on properties along the east side of Jarrettsville Pike, including 14301 Jarrettsville, and 14307 Jarrettsville, before traveling farther along strike into the residential neighborhood to the northeast. As detailed previously in the Distal Northeast Release and Migration Conceptual Model discussion, it is also believed that down-dip migration of hydrocarbon was influenced in this area by nearby supply well pumping at the commercial property located immediately northeast of the intersection at 14307 Jarrettsville Pike. This allowed for subsequent dissolved phase migration farther northeast along the bedrock contact. Sampling results at monitoring and supply wells farther north do not indicate further downdip migration at concentration of concern for other supply wells.

Eighteen monitoring wells are installed within the intersection and eastern Jarrettsville Pike properties, including 14301, 14307, 14311 and 14315 Jarrettsville Pike. Six of these wells have been consistently below standards throughout post-remediation monitoring and earlier: MW-36R, MW-38, MW-38B, MW-85, MW-181B, and MW-188D. The other 12 wells, MW-38C, MW-45, MW-45R, MW-54, MW-54B, MW-54C, MW-73C, MW-181A, MW-181C, MW-187A, MW-187B, and MW-187C, have had at least one detection above standard since system shutdown. Recent trends at MW-54 and MW-54B appear to be increasing, while trends appear to be stabilizing or decreasing at the remaining wells.

The maximum post-remediation MTBE concentration in monitoring wells within and immediately east / northeast of the intersection was 250 µg/L at MW-54B in the second quarter of 2026, and four monitoring wells have exceeded the established MTBE trigger levels (MW-45, MW-45R, MW-187A, and MW-187B). The maximum post-remediation benzene concentration in monitoring wells within and immediately east / northeast of the intersection was 1,400 µg/L at MW-187A in the third quarter of 2025, and four monitoring wells have exceeded the established benzene trigger levels (MW-54, MW-54B, MW-187A, and MW-187B).

Three properties in this area have in-use PSWs which are currently sampled: 14301 Jarrettsville Pike (though this property is serviced by a PSW located on 3410 Sweet Air Road to the southeast), 14307 Jarrettsville Pike has two supply wells located north of the MW-54 well cluster, and 14315 Jarrettsville

© 2026 Kleinfelder

Pike. PSW sampling results for these three properties have been below MDE drinking water standards for at least 15 years, including the 2.5 years of post-remediation monitoring, during which the maximum detected MTBE concentration was 0.84 µg/L at 14307 Jarrettsville Pike in September 2025.

Groundwater conditions within the intersection and immediately northeast, encompassing monitoring wells MW-187A, MW-187B, MW-187C, MW-54, MW-54B, and MW-54C, and private supply wells at 14307 Jarrettsville Pike warrant continued monitoring due to elevated MTBE and benzene monitoring well concentrations, and a potential migration pathway down dip to the 14307 Jarrettsville Pike supply wells. While supply well concentrations at 14307 Jarrettsville Pike have remained below drinking water standards, and recent trends at MW-187A, MW-187B, MW-187C, and MW-54C, appear stable to decreasing, the recalcitrant monitoring well concentrations above drinking water standards in proximity to the in-use private supply wells warrants continued monitoring.

The remaining twelve monitoring wells have significantly improved following approximately 18 years of active remediation as well as natural attenuation as supported by over 20 years of monitoring data, including 2.5 years of post-remediation monitoring. Six of these monitoring wells have remained consistently below standards throughout the post-remediation period. Six of the monitoring wells that have had at least one detection above standard since system shutdown, have since subsided or stabilized at levels that do not indicate remaining source or migration pathways of concern. PSWs serving 14301 Jarrettsville Pike and 14315 Jarrettsville Pike have been below MDE standards for at least 15 years, and are neither located near a source of elevated dissolved phase hydrocarbon concentrations, nor along a migration pathway, therefore there is no apparent complete exposure pathway between the source and a receptor which could lead to human or ecological exposure of unacceptable levels of gasoline-related constituents. Therefore, continued monitoring at monitoring wells MW-36R, MW-38, MW-38B, MW-38C, MW-45, MW-45R, MW-73C, MW-85, MW-181A, MW-181B, MW-181C and MW-188D, and PSWs serving 14301 Jarrettsville Pike and 14315 Jarrettsville Pike is no longer warranted.

Hampshire Glen and Southside Neighborhoods

There are 15 monitoring wells remaining on properties in the neighborhoods to the northeast, including 3501, 3506, and 3508 Hampshire Glen Court, and 3605A Southside Avenue, as well as six PSWs which continue to be sampled. LPH traveled though this portion of the site along strike to monitoring wells on 3508 Hampshire Glen Court, where further LPH migration was arrested due to remediation activities including a transverse line of recovery wells perpendicular to strike on 3508 Hampshire Glen Court.

© 2026 Kleinfelder

Additional recovery wells extended to 3605A Southside Avenue to address dissolved phase impacts. Deeper, elevated dissolved phase concentrations have been detected offset and down dip from the path of LPH migration as detailed in the Distal Northeast Release and Migration Conceptual Model discussion.

Ten of these wells have been consistently below standards throughout post-remediation monitoring and earlier: MW-47BB, MW-58, MW-91C, MW-138D, MW-168, MW-176, MW-178B, MW-179C, MW-182 and MW-184. The maximum MTBE detection was 10 µg/L in MW-179C in the third quarter of 2024, and the maximum benzene detection was 1.2 µg/L in MW-184 in the third quarter of 2024. The other five wells, MW-47C, MW-82B, MW-82D, MW-178C, and MW-189D, have had at least one detection above standard since system shutdown. None of the shallow A wells in this area have had detections above standard post-remediation. Recent MTBE trends at MW-47C and MW-82D appear to be increasing since 2022, though established trigger levels have not been exceeded Trends appear to be stabilizing or decreasing at the three remaining wells.

The maximum post-remediation MTBE concentration in monitoring wells within the Hampshire Glen and Southside neighborhoods was 170 µg/L at MW-82B in the fourth quarter of 2025, and MW-82B is the only monitoring well in this area that has exceeded its MTBE trigger level. Benzene has not been detected above the MDE drinking water standard of 5 ppb in this area post-remediation; the maximum benzene concentration was 1.7 µg/L at MW-178C in the first quarter of 2024 and has steadily declined since then.

Six properties in this area have in-use PSWs which are currently sampled: 3506, 3508, and 3600 Hampshire Glen Court, and 3605A, 3627A, and 3635 Southside Avenue. PSW sampling results for all of these properties except 3627A Southside Avenue have been below MDE drinking water standards for at least 17 years, including the 2.5 years of post-remediation monitoring. During post-remediation monitoring, there has been one MTBE detection above MDE standard at 3627A Southside Avenue, of 22 µg/L in January 2024. Since February 2024, concentrations at 3627A Southside Avenue have remained below MDE drinking water standards.

Certain monitoring wells and PSWs in the Hampshire Glen and Southside neighborhoods have been monitored for dissolved concentrations that migrated deeper and offset downdip from the original path of LPH migration due to the mechanism detailed in the Distal Northeast Release and Migration Conceptual Model discussion. This includes monitoring wells MW-47C and MW-82D which appear to have increasing MTBE concentrations, albeit below their trigger levels, as well as MW-82B and MW-189D which currently exhibit potentially stable to decreasing MTBE trends along this offset line of migration. While concentrations at private supply wells located at 3506 Hampshire Glen Court and 3627A and 3635

© 2026 Kleinfelder

Southside Avenue have been below MDE drinking water standards for at least 2.5 years, monitoring should also continue at these PSWs due to MTBE concentrations above standard at nearby monitoring wells and the potential migration pathway demonstrated by historic concentration trends at these PSWs.

The remaining eleven monitoring wells have significantly improved following approximately 18 years of active remediation as well as natural attenuation as supported by over 20 years of monitoring data, including 2.5 years of post-remediation monitoring. Ten of these monitoring wells have remained consistently below standards throughout the post-remediation period. MW-178C had MTBE detections above standard during the first two quarters following since system shutdown and MTBE concentrations at this well have since exhibited a clear decreasing trend, with MTBE concentrations below standard for the past two years. PSWs serving 3508 and 3600 Hampshire Glen Court and 3605A Southside Avenue have never had a detection above MDE standards, and are neither located near a potential source of elevated dissolved phase hydrocarbon concentrations, nor along a migration pathway, therefore there is no apparent complete exposure pathway between the source and a receptor which could lead to human or ecological exposure of unacceptable levels of gasoline-related constituents. Therefore, continued monitoring at monitoring wells MW-47BB, MW-58, MW-91C, MW-138D, MW-168, MW-176, MW-178B, MW-178C, MW-179C, MW-182 and MW-184, and PSWs serving 3508 and 3600 Hampshire Glen Court and 3605A Southside Avenue is no longer warranted. Furthermore, this dense network of monitoring wells located on the 3501 Hampshire Glen Court property were installed for investigation of the small-scale controls on site hydrogeology where the space was available to do so. These monitoring wells were not intended for extended monitoring

4.6 ALTERNATE SOURCE IMPACTS

Multiple other potential sources of hydrocarbon detections and impacts are known or suspected within the site investigation and private supply well monitoring area. These include other gasoline service stations, fire department training activities, and residential / commercial uses such as gasoline storage, use, transfer; use of plumbing compounds and solvents; and disposal of waste materials into the multiple on-lot septic systems in the area. Groundwater monitoring data will continue to be evaluated for indicators of potential releases from other sources.

The 2016 CSM Report summarized several potential alternate source locations, however only one remains within the current project area. The MTBE concentrations at the 3627A Southside Avenue property have been retained within the CSM, based on extensive additional characterization work and monitoring as recommended in the 2016 CSM Report, and detailed within this CSMU Report.

© 2026 Kleinfelder

As noted in the Spatial Distribution of Trends discussion, it is suspected that fluctuating BTEX concentrations detected at MW-40 located on 14223 Robcaste Road may be in part attributed to stormwater runoff from commercial properties along Jarrettsville Pike. Dissolved phase composition at MW-40 has shown relatively higher concentrations of BTEX compounds than MTBE when compared with other monitoring wells, and MW-40 is a shallow well screened from 5 to 30 feet below top of casing and is located adjacent to a stream channel which receives stormwater runoff from commercial properties on Jarrettsville Pike. Concentration measured at MW-40 are likely influenced in part by stormwater runoff and associated groundwater elevation fluctuations, representing a localized anomaly that has not contributed to elevated or fluctuating concentrations in other nearby wells.

5 CSM CONCLUSIONS

Key aspects of the CSM determined through 20 years of characterization and monitoring, including approximately 18 years of active remediation, and 2.5 years of post-remediation monitoring are summarized as follows:

Hydrogeology, Fate, and Transport

- The groundwater potentiometric gradient is toward the topographic valleys extending northeast and southwest from the inactive service station property (converging from the valley sides and from below). Unimpacted groundwater discharges to tributaries of the Sawmill Branch of Little Gunpowder Falls and the Greene Branch of Gunpowder Falls.
- Influenced by the anisotropy of the metamorphic foliation and constrained by the converging potentiometric gradient, LPH and dissolved-phase hydrocarbons migrated along strike, coincident with the longitudinal axis of these topographic valleys extending from the inactive service station property. This migration principally occurred in the unconfined shallow groundwater (water table) interval.
- Vertical downward migration of LPH and dissolved-phase hydrocarbons is impeded by several factors:
    - The LPH, gasoline, is a non-aqueous phase liquid with a specific gravity less than water.
    - There is an upward hydraulic gradient beneath the topographic valleys extending northeast and southwest from the former service station property.
    - Groundwater extraction for remediation has inhibited vertical downward migration and has instead induced an upward hydraulic gradient in remediation areas.The porosity, permeability, fracture frequency, and fracture aperture decrease with depth in the fractured rock aquifer with maximum permeability occurring near the water table in the shallow weathered transition zone between saprolite and more competent bedrock.

Response to Remediation

- The combination of total fluids pumping, multi-phase vacuum extraction, and soil vapor extraction was effective at removing LPH and dissolved-phase mass while containing and contracting the extent of dissolved-phase hydrocarbons in groundwater, resulting in system shutdown approval in December 2023.
- LPH that once extended in a linear, northeast-southwest direction over a distance of 1,870 feet has not been measurable in any of the more than 300 monitoring and recovery wells since 2008.

© 2026 Kleinfelder

- Dissolved-phase hydrocarbons in groundwater have been significantly reduced in concentration and retracted in extent due to remediation activities.

Recent Conditions

- Evidence of MTBE-specific biodegradation indicates that natural attenuation processes act to reduce the mass and limit the migration of residual MTBE in the aquifer.
- Collectively, the groundwater conditions at the inactive station and other properties west of the intersection have significantly improved following approximately 18 years of active remediation. Most of the wells west of the intersection have remained consistently below standards throughout the post-remediation period. Of the wells that have had at least one detection above standard since system shutdown, concentrations have since subsided or stabilized at levels that do not indicate remaining source or migration pathways of concern.
- The intersection and adjacent properties east of Jarrettsville Pike is where the highest concentrations remain. This is the area immediately downgradient from the UST release area where direct remediation within the intersection was delayed until the intersection reconstruction project was completed by SHA in 2014. The interior location of these isolated, residual concentrations limits risk of migration to potential receptors.
- There are 15 monitoring wells remaining on properties to the northeast, including 3501, 3506, and 3508 Hampshire Glen Court, and 3605A Southside Avenue, as well as six PSWs which continue to be sampled. Ten of these monitoring wells have been consistently below standards throughout post-remediation monitoring and earlier. The other 5 monitoring wells have had at least one detection above standard since system shutdown. Recent MTBE trends at MW-47C and MW-82D appear to be increasing though established trigger levels have not been exceeded, while trends appear to be stabilizing or decreasing at the three remaining wells. Six properties in this area have in-use PSWs which are currently sampled: 3506, 3508, and 3600 Hampshire Glen Court, and 3605A, 3627A, and 3635 Southside Avenue. PSW sampling results for all of these properties except 3627A Southside Avenue have been below MDE drinking water standards for at least 17 years.
- A pulse of dissolved MTBE migrated through distal northeast private supply wells at 3627A and 3635 Southside Avenue. This pulse migrated along bedrock strike parallel to, but off-set from, the original line of LPH and MTBE migration, evading groundwater capture. This is attributed to early, near-source, down-dip entrainment by the private supply well at 14307 Jarrettsville Pike. The pulse of MTBE experienced diminishing concentrations along its flow path due to dispersion. The pulse peak has since passed through the supply wells at 3627A and 3635 Southside Avenue. MTBE concentrations have been below the State Action Level of 20 µg/L since February 2024. The MTBE

© 2026 Kleinfelder

concentration attenuated to less than the State Action Level of 20 µg/L prior to the pulse peak reaching the supply well at 3635 Southside Avenue, and is not expected to migrate farther to the northeast above the action level.

Risk Summary

Drawing upon over 20 years of characterization and monitoring data, including approximately 18 years during active remediation, and now 2.5 years of post-remediation monitoring, it is well understood where potentially complete exposure routes of concern remain, comprised of a potential source (elevated MTBE or benzene groundwater concentrations), potential migration pathway, and potential receptor (private supply well). At monitoring wells where concentration increases occurred following system shutdown and re-equilibration within the aquifer, most have since stabilized or decreasing trends have been established. At the few locations which currently exhibit potential increasing trends, these concentrations are generally consistent with historic levels in the vicinity, and it is expected that future trends will level off and then ultimately decrease aided by natural attenuation since most of the source has already been removed.

Additionally, it is understood where there is no longer a potential exposure of concern due to lack of either source, demonstrated migration pathway, or potential receptor. This understanding should inform site management decisions going forward as monitoring should continue in areas of potential concern and can cease in locations without a potential exposure of concern, as detailed further in the following section.

This approach is consistent with literature and scientific consensus on remediation and natural attenuation of petroleum release sites, including USEPA's *Reassessing Exposure Threats from Petroleum Underground Storage Tank Releases* (EPA OUST, 2025) and ASTM *Standard E3488-25 Moving Sites to Closure (MStC) for Petroleum Underground Storage Tank (UST) Releases* (ASTM 2025). Petroleum plumes tend to naturally stabilize and degrade and contract instead of expand and increase, particularly when there is limited source strength such as the case for this site following extensive remediation and indication of natural biodegradation, and monitoring of areas with low potential threat to receptors is unnecessary.

6 PROPOSED PATH TO CLOSURE

This section provides a path forward to progress to case closure while maintaining continued protection of public health and the environment. More than 20 years of extensive characterization, remediation, and monitoring have been conducted resulting in marked reduction in hydrocarbon mass (LPH and dissolved phase) and contraction of the dissolved-phase hydrocarbon constituents in groundwater. Accordingly, the case has progressed, including the gradual conversion of all recovery wells to monitoring wells, culminating with remediation system shutdown in December 2023; multiple rounds or monitoring well abandonment totaling 252 wells abandoned and suspension of sampling at 3 unused supply wells; and reduction of the private supply well sampling program to the current 15 wells. The data and analysis presented in this CSM Update support continued progression of the case to focus on the areas and conditions where a potential exposure path remains between dissolved phase contamination source and potential receptors, as discussed below.

6.1 CASE PROGRESSION AND CLOSURE FRAMEWORK

The framework for case progression and closure are outlined in the September 2008 Consent Decree and the June 2018 Order of Resolution, with key provisions highlighted below.

6.1.1 2008 Consent Decree

Paragraph 32 states "*The remedial goal is to return the groundwater to conditions that are protective of public health and the environment or achieve contamination levels at or below the Department's current groundwater standards and action levels where possible as determined by the Department. It is acknowledged by both parties that the remedial action may employ natural attenuation and may also include engineering or institutional controls*."

This paragraph acknowledges the role natural attenuation may play in remediation, as well as potential use of engineering or institutional controls, and allows for risk-based alternative closure criteria if it is demonstrated that groundwater to conditions that are protective of public health and the environment.

Paragraph 34 states "*The Department shall determine when remediation is completed to an extent that is protective of public health and the environment. It is recognized that the Department may determine that remediation is complete on one or more parcels while still requiring remediation*

© 2026 Kleinfelder

for other parcels. The Department, in its sole discretion, will issue a "no further action" approval on a parcel by parcel basis."

This acknowledges that remediation and monitoring activities may be complete on some properties while additional action is required on other properties. Accordingly, MDE has the discretion to issue "no further action" approval for individual parcels.

6.1.2 2018 Order of Resolution

Paragraph 8 established four flowcharts outlining expectations to progress the case specific to conversion of a recovery well to a monitoring well, abandoning a monitoring well, discontinuation of private supply well sampling and conveyance or removal of POETs, and property-specific no further action determination. Paragraph 8 indicates that MDE agrees to consider the flowcharts "*in addition to considering data such as proximity of properties to the 2006 release and areas of documented petroleum-related impacts, current concentrations in private supply wells, historical sampling results and trends and proximity to groundwater monitoring / recovery wells and remediation systems*…"

Exhibit C, Flowchart 1: Conversion of Recovery Well (RW) to Monitoring Well (MW) outlines the process to seek MDE approval for shutting down and converting recovery wells to monitoring wells, including pathways for wells with concentrations below MDE standards for at least one year (concentration threshold), as well as a risk-based alternative. Flowchart 1 has been successfully used to support requests for RW to MW conversions utilizing both the concentration threshold criteria and the risk based alternative approach, and MDE has approved requests under both approaches, resulting in the conversion of all remaining RWs to MWs when system shutdown approval was granted in December 2023.

Exhibit D, Flowchart 2: Monitoring Well (MW) Sampling and Abandonment outlines the process to seek MDE approval for discontinuing sampling and gauging and abandonment of monitoring wells, including pathways for wells with concentrations below MDE standards for at least one year which are not needed for potentiometric mapping or rebound monitoring, as well as a risk-based alternative. Flowchart 2 has been used to support requests to discontinue sampling and gauging and abandon monitoring wells utilizing the concentration threshold criteria and the risk based alternative approach. MDE has approved some, but not all requests based on concentration

© 2026 Kleinfelder

threshold criteria, but no monitoring wells have been approved for abandonment by MDE under the risk-based approach. A proposed risk-based framework for discontinuing monitoring and abandoning monitoring wells is provided below.

Exhibit E, Flowchart 3: Private Supply Well (MW) Sampling outlines the process to seek MDE approval for discontinuing sampling a PSW and conveyance or removal of a POET, if the concentration threshold of PSW sample results below MDE standards for at least two years is met. Flowchart 3 has been used to support requests to discontinue PSW sampling and convey or remove a POET utilizing the concentration threshold criteria, and MDE has approved some but not all requests.

Exhibit F, Flowchart 4: No Further Action Request outlines the process to seek MDE approval for No Further Action (NFA) requests by property, if there are no active RWs, all MWs have been abandoned, and no PSWs are required to be sampled on the property. The Consent Decree and Flowchart 4 has been used to support NFA requests for three properties, which MDE has approved.

6.1.3 Case Progression Framework Summary

The 2008 Consent Decree acknowledges and allows for the use of natural attenuation, institutional and engineering controls in the remediation and closure strategy, in addition to compliance with MDE standards, to ensure protection of human health and the environment. The Consent Decree also allows for approval of No Further Action on some parcels, while activities continue to ensure protectiveness.

With the Consent Decree as the foundation, the 2018 Order of Resolution outlines pathways to progress the case, including discontinuing sampling and abandonment of monitoring wells for wells which have been below MDE standards for at least 1 year and are not needed for potentiometric mapping or rebound monitoring, as well as a risk-based alternative. To date, MDE has approved monitoring well abandonments based on the concentration threshold, though some wells which met the concentration requirement were denied by MDE for rebound monitoring. Other monitoring wells proposed for abandonment with a risk basis were denied by the MDE for abandonment. MDE has also approved discontinuation of sampling and conveyance or removal of POETs which met the concentration threshold and denied others. The data and analysis presented in this CSM Update, including 2.5 years of post-remediation monitoring for rebound, should serve as a basis for future case progression decisions as the areas requiring continued monitoring

© 2026 Kleinfelder

and focus have been described, and the locations which do not require additional monitoring for rebound or other condition of concern because the existing data set has confirmed low threat of an exposure route of concern, as summarized below.

6.2 PROPOSED RISK-BASED ALTERNATIVE CRITERIA FOR DISCONTINUATION AND ABANDONMENT OF MONITORING WELLS

The 2018 Consent Decree and 2018 Order of Resolution allow for risk-based alternatives if conditions are demonstrated to be protective of human health and the environment. This is consistent with recent literature and guidance on management and closure of petroleum release sites from USEPA[1] (2025) and ASTM[2] (2025), which encourage a threat assessment approach to "examine the current conditions at UST release sites and identify specific sources, pathways, and receptors that could lead to contaminant exposure to human or ecological receptors" (EPA OUST, 2025) to better inform site activities and move sites toward closure.

The threat assessment approach utilizes risk-based decision making and exposure assessment methodologies with focus on whether there is a complete exposure pathway (e.g. evaluating will contaminants reach a potential receptor at concentrations of concern), and does not quantify potential harm to a receptor as a risk assessment does.

Consistent with the threat assessment approach and alternative groundwater closure criteria recommended in the ASTM MStC Standard, the following risk-based alternative criteria are proposed for consideration of monitoring well sampling discontinuation and abandonment:

1. Decreasing Concentration Trends – The 2018 Order of Resolution Flowchart 2 establishes one year of concentrations below MDE standards as a threshold criterion for monitoring well sampling discontinuation and abandonment. At monitoring wells which do not meet the one-year threshold criteria, two years of decreasing trends is proposed as an alternative criterion to consider monitoring well sampling discontinuation and abandonment. This may be evaluated with the GWSDAT half-life calculation, and/or Mann Kendall analysis. Decreasing concentration trends demonstrate that natural attenuation will ultimately achieve concentrations compliant with MDE standards as plumes degrade and contract once source has been removed.

[2] *ASTM Standard E3488-25 Moving Sites to Closure (MStC) for Petroleum Underground Storage Tank (UST) Releases (ASTM, 2025)*

© 2026 Kleinfelder

2. Location Relative to Migration Pathways – The site is well-characterized and migration pathways along which LPH and dissolved phase COCs traveled is well understood, as detailed within this CSM Update. The location of wells relative to these migration pathways should be considered when evaluating monitoring wells for sampling discontinuation and abandonment. For the bedrock structural setting in which this release occurred and migrated, orientation of monitoring and supply wells relative to the secondary porosity features which influenced LPH and dissolved phase migration are more significant than distance alone. Travel distance along the migration pathways (e.g. along strike and offset, down-dip from strike in the NE) has been significantly greater than travel distances perpendicular to strike as shown in the 3-dimensional visualizations (Graphics 24-27). Accordingly, there is low threat of migration of dissolved phase COCs away from the known migration pathways towards PSWs, and does not require additional monitoring.

3. Mass-Limited Conditions – As noted in the ASTM MStC Standard, "the mass-limited criterion can be applied to assess COC concentrations at the point of exposure (such as a water supply well or surface water body), the stability or attenuation rates or both of COCs in groundwater, and the effectiveness of groundwater remediation." This alternative groundwater criterion is applicable "where the mass flux/discharge of COCs in groundwater is sufficiently small to prevent COC concentrations from exceeding background or corrective action levels at points of exposure (such as water supply wells or surface water bodies). (ASTM 2025)." At this stage for this site, the mass-limited criterion may be applied to monitoring wells with stable COC concentrations that are not acting as a source of dissolved phase COCs above MDE standards at PSWs. Though concentrations may exist in a monitoring well above the MDE standard, that concentration may represent a relatively small mass of contaminants and mass flux, which does not contribute to concentrations of concern downgradient or in nearby PSWs due to natural attenuation and other factors, e.g. lack of a complete migration pathway, contribution from nearby cleaner groundwater, etc. Therefore monitoring wells exhibiting stable, mass-limited conditions are low threat and do not require additional monitoring.

These alternative criteria, evaluated either on their own, or together, are recommended as criteria when considering monitoring well sampling discontinuation and abandonment according to the risk-based approach which both the 2008 Consent Decree and 2018 Order of Resolution allow.

© 2026 Kleinfelder

6.3 PROPOSED FOCUS AREAS

In the 2.5 years of post-remediation monitoring, hydrocarbon concentrations at 26 of the 51 current monitoring wells have remained below MDE standards, and since February 2024 concentrations at all 15 PSWs have been below MDE standards. Of the 25 monitoring wells that have had at least one dissolved phase constituent (MTBE or benzene) detection above standard since system shutdown, 13 exhibit trends generally consistent with pre-shutdown trends and have not exceeded a trigger level, and 12 wells showed some level of rebound in concentrations compared to when the system was operating, including eight wells that have had at least one trigger value exceedance for MTBE or benzene. Review of more recent post-remediation monitoring well data indicates that most monitoring wells which exhibited some level of increased concentrations above MDE standards, or trigger levels, concentration trends over the last 1 to 2 years have been stabilizing or decreasing. Four monitoring wells currently exhibit potentially increasing trends, MW-54 and MW-54B just east of the intersection of MD Routes 145 and 146, and MW-47C and MW-82D, which are located farther to the northeast along the offset, downdip path of deeper dissolved phase migration, and it should be noted the increasing trends in these two wells appears to have started prior to system shutoff.

Drawing on more than 20 years of site characterization, remediation, and monitoring data, including the groundwater response observed during the two-and-a-half-year post-shutdown monitoring period, the current conceptual site model identifies where potential drinking-water concerns remain and require continued focused monitoring, and where no remaining exposure concern exists because one or more elements of the source-pathway-receptor linkage is absent: no remaining source of concern, no complete migration pathway of concern, or no potential receptor.

- Properties west of the intersection of MD Routes 145 and 146, including the inactive station and other properties on the west side of Jarrettsville Pike, Papermill Road, and Robcaste Road, are considered low threat due to the absence of a complete source → pathway → potential receptor exposure route and do not warrant continued monitoring. Most monitoring wells and all PSWs meet the concentration threshold criteria established in Flowchart 2 and 3, respectively. The few monitoring wells which have had at least one exceedance of MDE standards in the last year meet at least one of the proposed alternative groundwater criteria presented above in Section 6.2: decreasing trends, not located along a pathway for migration of concern, or stable, mass-limited conditions which do not pose a threat to a point of compliance.
- The intersection and 14307 Jarrettsville Pike immediately to the east require continued monitoring at the MW-187 cluster, the MW-54 cluster and the 14307 Jarrettsville Pike PSW due

© 2026 Kleinfelder

to ongoing elevated concentrations and potentially increasing concentrations at MW-54 and MW-54B, and a potential migration pathway to private supply wells on 14307 Jarrettsville Pike. Other monitoring and supply wells located at properties along the east side of Jarrettsville Pike do not warrant continued monitoring due to the absence of a complete source → pathway → potential receptor exposure route as one or more of the proposed alternative groundwater criteria are met, and are therefore considered low threat.

- Farther northeast within the Hampshire Glen and Southside neighborhoods, certain monitoring wells and PSWs near the apparent offset, down dip path of dissolved phase migration warrant continued monitoring, including MW-47C, MW-82B, MW-82D, and MW-189D and PSWs at 3506 Hampshire Glen Court, 3627A Southside Avenue, and 3635 Southside Avenue. Other monitoring and supply wells located at properties within the Hampshire Glen and Southside neighborhoods do not warrant continued monitoring due to the absence of a complete source → pathway → potential receptor exposure route as one or more of the proposed alternative groundwater criteria are met, and are therefore considered low threat.

The proposed focus areas and wells for continued monitoring are shown on Figure 16.

6.4 PROPOSAL FOR FUTURE MONITORING AND ABANDONMENTS

6.4.1 Monitoring Wells and Private Supply Wells Proposed for Continued Monitoring

Monitoring wells proposed for continued monitoring include six wells in the intersection area (MW-187A, MW-187B, MW-187C, MW-54, MW-54B, and MW-54C), and four wells within the Hampshire Glen and Southside Avenue neighborhoods (MW-47C, MW-82B, MW-82D, and MW-189D). Private supply wells at four properties are proposed for continued monitoring, including 14307 Jarrettsville Pike, 3506 Hampshire Glen Court, 3627A Southside Avenue, and 3635 Southside Avenue. Quarterly sampling at the ten monitoring wells (according to current methodology) and four PSWs is proposed to evaluate groundwater conditions and trends relative to MDE standards and the proposed alternative groundwater criteria. For monitoring wells which exceed the established trigger levels, monthly sampling will be conducted until either three consecutive samples indicate concentrations below the trigger level, or three consecutive decreasing concentration results, at which time quarterly sampling will resume. When remaining monitoring wells have established stable or decreasing trends, sampling frequencies may be re-evaluated to semi-annual frequency. Proposed monitoring well activities are detailed in Appendix L1, which includes

© 2026 Kleinfelder

a summary of recent groundwater concentrations, trend analysis and proposed future activity along with rationale incorporating concentration threshold or proposed alternative groundwater criteria, as applicable.

6.4.2 Monitoring Wells Proposed for Abandonment

Thirty-eight monitoring wells are proposed for abandonment, including 18 monitoring wells to the west of the intersection, 11 monitoring wells on properties on the eastern side of Jarrettsville Pike, and 9 monitoring wells on 3501 Hampshire Glen Court. Drawing upon over twenty years of data as detailed within this CSM Update, including two and a half years of post-remediation monitoring, locations with rebound in dissolved phase concentrations within a potential migration pathway that present a potential exposure concern are understood and there is no remaining exposure route of concern to the west of the intersection, or beyond the down-dip, deeper dissolved phase migration pathway to the northeast. Twenty-seven of the monitoring wells proposed for abandonment have been below MDE standards for at least 1 year, and the other 11 monitoring wells meet at least one of the proposed alternative groundwater criteria, as noted in Appendix L1.

6.4.3 Monitoring Wells Proposed to Discontinue Monitoring and Retain

Three monitoring wells are proposed to discontinue sampling, while the monitoring wells are retained for potential future monitoring. This includes monitoring wells located along the dissolved phase migration pathway including two which have been below MDE groundwater standards for over a year, MW-178C, and MW-138D, and one well with decreasing trends and mass-limited MTBE concentration just above standards, MW-38C. These wells may be proposed for abandonment once stable to decreasing concentration trends are established at the remaining monitoring wells northeast of the intersection.

6.4.4 Private Supply Wells Proposed to Discontinue Sampling

The 11 private supply wells currently sampled semi-annually are proposed to discontinue sampling. Each of these PSWs has met the concentration threshold criteria from Flowchart 3 of all results below the MDE standards for at least two years; all dissolved phase gasoline COCs have been below MDE standards for at least 14 years. Nine of the PSWs proposed to discontinue sampling are on properties that either have no other monitoring and activities ongoing, or existing monitoring wells are proposed to discontinue sampling and abandon, consistent with the second and third criteria on Flowchart 3: 14217 Robcaste Rd, 14223 Robcaste Road, 3313 Paper Mill Road, 14240 Jarrettsville Pike, 14242 Jarrettsville Pike, 14258

© 2026 Kleinfelder

Jarrettsville Pike, 14301 Jarrettsville Pike, 14315 Jarrettsville Pike, and 3600 Hampshire Glen Court. Two of the PSWs proposed to discontinue sampling are on properties with monitoring wells proposed to continue sampling, 3508 Hampshire Glen Court, and 3605A Southside Avenue. This is a deviation from the third criteria on Flowchart 3, however sampling discontinuation is proposed because concentrations have never exceeded MDE action levels at these PSWs, and 2.5 years of post-remediation monitoring has confirmed that there is no exposure threat at these PSWs.

6.4.5 Summary of Proposed Monitoring and Abandonment Activity

The table below summarizes the proposed changes to the groundwater monitoring program and monitoring well abandonments:

Summary of Current and Proposed Monitoring Activities and Well Abandonments

	Current Totals	Proposed Totals August 2026
Existing Monitoring Wells	**53**	**13**
Sampled	51	10
- Quarterly Sampling	25	10
- Semi-Annual Sampling	26	0
- Suspend Sampling at MWs	0	3
Suspend Sampling at Inactive Supply Wells	3	3
Active Private Supply Well Previously Sampled as a MW	1	1
Approved for Abandonment, status under review	2	0
Abandoned Wells	**252**	**292**
Total Monitoring Wells	**309**	**309**
Private Supply Wells		
- Private Supply Wells Sampled Monthly	1	0
- Private Supply Wells Sampled Quarterly	3	4
- Private Supply Wells Sampled Semiannually	11	0
Total Private Supply Wells	**15**	**4**

Note: Review of previous monitoring well abandonment events updated in current totals; MW-69 and MW77R approved for abandonment included in existing well total while status under review.

The proposed monitoring program is Shown on Figure 16 and detailed in Appendix L1 and L2.

6.5 REQUEST FOR PARCEL-SPECIFIC NO FURTHER ACTION APPROVALS

As the case has progressed and MDE has approved remediation system shutdown, well abandonments and discontinuation of private supply well sampling at several properties, consistent with Flowchart 4, the following 16 properties are eligible for NFA determination by the MDE:

© 2026 Kleinfelder

3503 Hampshire Glen Court
3505 Hampshire Glen Court
3505 Hampshire Glen Court
3604 Hampshire Glen Court
3606 Hampshire Glen Court
14330 Jarrettsville Pike
14208 Robcaste Road
14219 Robcaste Road
14221 Robcaste Road
14225 Robcaste Road
3525 Southside Avenue
3605B Southside Avenue
3605C Southside Avenue
3605D Southside Avenue
3410 Sweet Air Road
3418 Sweet Air Road

Previous activities at these properties included installation, gauging and sampling of monitoring wells, some of which were also operated as recovery wells. Additionally, private supply sampling was conducted at PSWs in use. MDE has approved cessation of all remediation and monitoring activities at these properties, including abandonment of all monitoring wells (Appendix C), and discontinuation of PSW sampling. Monitoring well abandonment records have been submitted to the Baltimore County Health Department, with copies provided to the MDE. Therefore, no further action approval is respectfully requested at the properties listed above. As additional properties meet the criteria outlined in Flowchart 4, pending approval of additional monitoring well abandonments and discontinuation of private supply well sampling, additional requests for NFA approval will be submitted to the MDE until final NFA approval is achieved for the case.

APPENDIX A

SUMMARY OF INVESTIGATIONS AND ASSESSMENT ACTIVITIES

© 2026 Kleinfelder

APPENDIX A
SUMMARY OF INVESTIGATIONS AND ASSESSMENT ACTIVITIES
FEBRUARY 2006 – JUNE 2016

1.1 INITIAL INVESTIGATION

Assessment activities were initiated in February 2006 in response to the discovery of LPH in existing monitoring wells following a release of approximately 26,000 gallons of gasoline from the former Exxon service station. These monitoring wells had been installed to comply with COMAR regulations applicable to High Risk Groundwater Use Areas.

The underground storage tanks (USTs), associated piping, and dispenser islands were removed from the service station property between March 4, 2006 and April 10, 2006. These activities were reported to the MDE in the Tank Excavation Assessment Report (GSC/Kleinfelder, 2006b). Prior to UST removal activities, the service station features consisted of a canopy covering three dispenser islands, two 8,000-gallon gasoline USTs, one 10,000-gallon diesel UST, one 12,000-gallon gasoline UST and associated single-walled fiberglass piping. The USTs were installed in 1985 and were constructed of double-walled, fiberglass-coated steel. In July 1992 and May 1997, one 1,000-gallon fiberglass used-oil UST and one 1,000-gallon fiberglass heating oil UST were removed from the service station property, respectively.

By June 2006, the following assessment activities had been completed (Kleinfelder, 2006a):

- Advancement of 213 boreholes, of which 208 were completed as monitoring wells;
- Acquisition of three bedrock core samples;
- Sampling of 273 private supply wells within an approximately ½-mile radius from the former service station property;
- Completion of four seismic survey profiles;
- Completion of five electrical resistivity imaging profiles;
- Completion of one area microgravity survey and four microgravity survey profiles;
- Downhole geophysics/logging of 11 bedrock boreholes;
- Completion of hydraulic profiling with blank Flexible Liner Underground Technologies (FLUTe ™) liners in three bedrock boreholes;
- Installation of custom FLUTe™ water liners with discrete sampling ports in four bedrock boreholes;
- Implementation and analysis of two constant-rate aquifer pumping tests – one in the northeast and one in the southwest;

© 2026 Kleinfelder

- Implementation of 127 slug tests in 42 monitoring wells;
- Completion of soil gas sampling adjacent to buildings on six properties in the northeast;
- Geologic inspection of the tank field excavation area;
- Collection and analysis of 1,483 groundwater samples;
- Collection and analysis of 31 surface water (stream and pond) samples;
- Implementation of 170 rounds of groundwater potentiometric surface and product thickness level gauging events.

1.2 PRIVATE SUPPLY WELL (PSW) SAMPLING / POINT OF ENTRY TREATMENT (POET) SYSTEMS

Since 2006, more than 270 private supply wells surrounding the former service station have been sampled by ExxonMobil. Starting on February 19, 2006, supply wells on three properties in the immediate vicinity of the station were sampled (3313 Paper Mill Road, 3305 Paper Mill Road and 14242 Jarrettsville Pike). The sampling program was expanded at the MDE's direction on February 21, 2006, to include properties within a ½-mile radius of the former service station property to the southwest (MDE, 2006). The program was expanded again in March 2006 to include properties within a ¼-mile radius of the station to the northeast. Based on MDE correspondence dated March 10, 2006, a precautionary round of sampling was conducted for private supply wells within a ½-mile radius of the station that had not yet been sampled.

Over the course of the project, 15 point-of-entry (POET) systems have been installed and maintained by ExxonMobil in cooperation with the MDE:

- 14242 Jarrettsville Pk. (installed 3/4/2006)
- 3507 Hampshire Glen Ct. (installed 3/16/2006)
- 3606 Hampshire Glen Ct. (installed 3/22/2006)
- 3608 Hampshire Glen Ct. (installed 3/22/2006)
- 3503 Hampshire Glen Ct. (installed 4/27/2006)
- 3506 Hampshire Glen Ct. (installed 4/27/2006)
- 3508 Hampshire Glen Ct. (installed 4/27/2006)
- 3604 Hampshire Glen Ct. (installed 4/28/2006)
- 14301 Jarrettsville Pk. (installed 8/15/2006)
- 3313 Paper Mill Rd. (installed 5/16/2007)
- 14406 Katie Rd. (7/5/2007)
- 14307 Jarrettsville Pk. (installed 8/7/2007)
- 14405 Jarrettsville Pk. (installed 9/12/2008)
- 3605B Southside Ave. (installed 10/20/2008)
- 3627A Southside Ave. (installed 10/22/2013)

© 2026 Kleinfelder

Of these 15 POETs, ExxonMobil continues to maintain one at 3627A Southside Ave.

1.3 SOIL VAPOR SAMPLING

MDE evaluates indoor air hazards based on the Environmental Protection Agency (EPA) Regional Screening Level (RSL) table, using a tiered approach.

- Tier 2 (screening) - Provided indoor air contamination is below acceptable risk thresholds, soil gas concentrations below the Tier 2 screening values do not require additional monitoring or assessment, as long as the known source conditions are stable.
- Tier 1 (action) - When soil gas concentrations are between the Tier 2 screening levels and the Tier 1 action levels, and indoor air is "acceptable," long-term monitoring/source reduction is required. When soil gas concentrations exceed the Tier 1 values, remedial measures are necessary.

All soil gas sampling was discontinued by August 2014 with the approval of the MDE (MDE, 2011; MDE, 2014). All soil gas concentrations were below Tier 2 screening levels when sampling ended. Historically, 99.4% of all samples for all six properties were below Tier 1 action levels.

1.4 GROUNDWATER SAMPLING/MONITORING

Initial Assessment (2006-2007)

As part of the initial assessment, 208 monitoring wells were installed from February 18, 2006 through May 17, 2006 (Kleinfelder, 2006b).

FLUTe™ liners were installed in four C zone monitoring wells to obtain discrete-depth sampling data and to protect against the potential for vertical migration during early stages of investigation as the hydrocarbon distribution was being investigated.

Expanded MW Network (2008-2010)

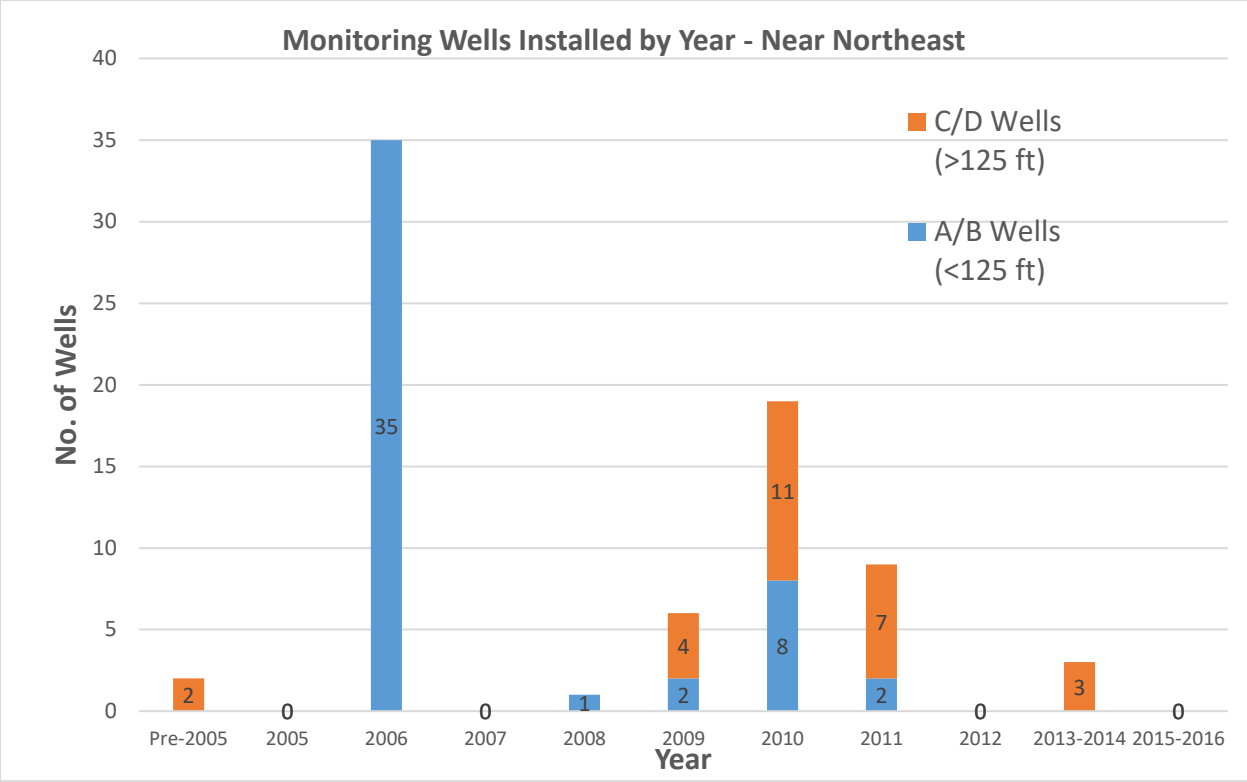
In August 2007, a phased expansion of the monitoring well network was agreed to by ExxonMobil and the MDE (MDE, 2007). Between 2008 and 2010, 26 wells were installed and downhole geophysical logging was conducted on wells with a depth greater than 250 ft-bgs ("C Zone" wells).

Initial sampling of the wells following installation indicated dissolved phase hydrocarbons were minimal to non-detect, with the exception of low-level MtBE concentrations in MW-175C and higher concentrations of MtBE in MW-172C (Kleinfelder, 2010), both of which are now non-detect.

© 2026 Kleinfelder

As directed by the MDE, the C zone wells of the expanded monitoring well network were constructed and located to replicate private supply well construction, ultimately to serve in lieu of private supply well sampling.

Near Northeast Area Investigation (2009-2011)



Due to increasing MtBE trends associated with two supply wells in the near northeast (3506 Hampshire Glen Court and 14307 Jarrettsville Pike) further assessment activities were conducted in the "near northeast area" from the former service station property (Figure 4). The near northeast investigation encompassed the following activities:

- Monitoring well installation
- Increased sampling of existing monitoring wells
- HydraSleeve™ interval and composite sampling of the open borehole portions of "C" wells
- Packer sampling
- Water usage assessment
- Geophysical investigation, including borehole logging, surface geophysics (microgravity and electrical resistivity), and tomography (electrical resistivity and seismic)

Between March 2009 and March 2011, 27 additional monitoring wells were installed, and between April 2009 and December 2010, nine additional recovery wells were activated. The remedial activities implemented concurrently with the near northeast investigation successfully reversed increasing supply well concentration trends (Kleinfelder, 2011a).

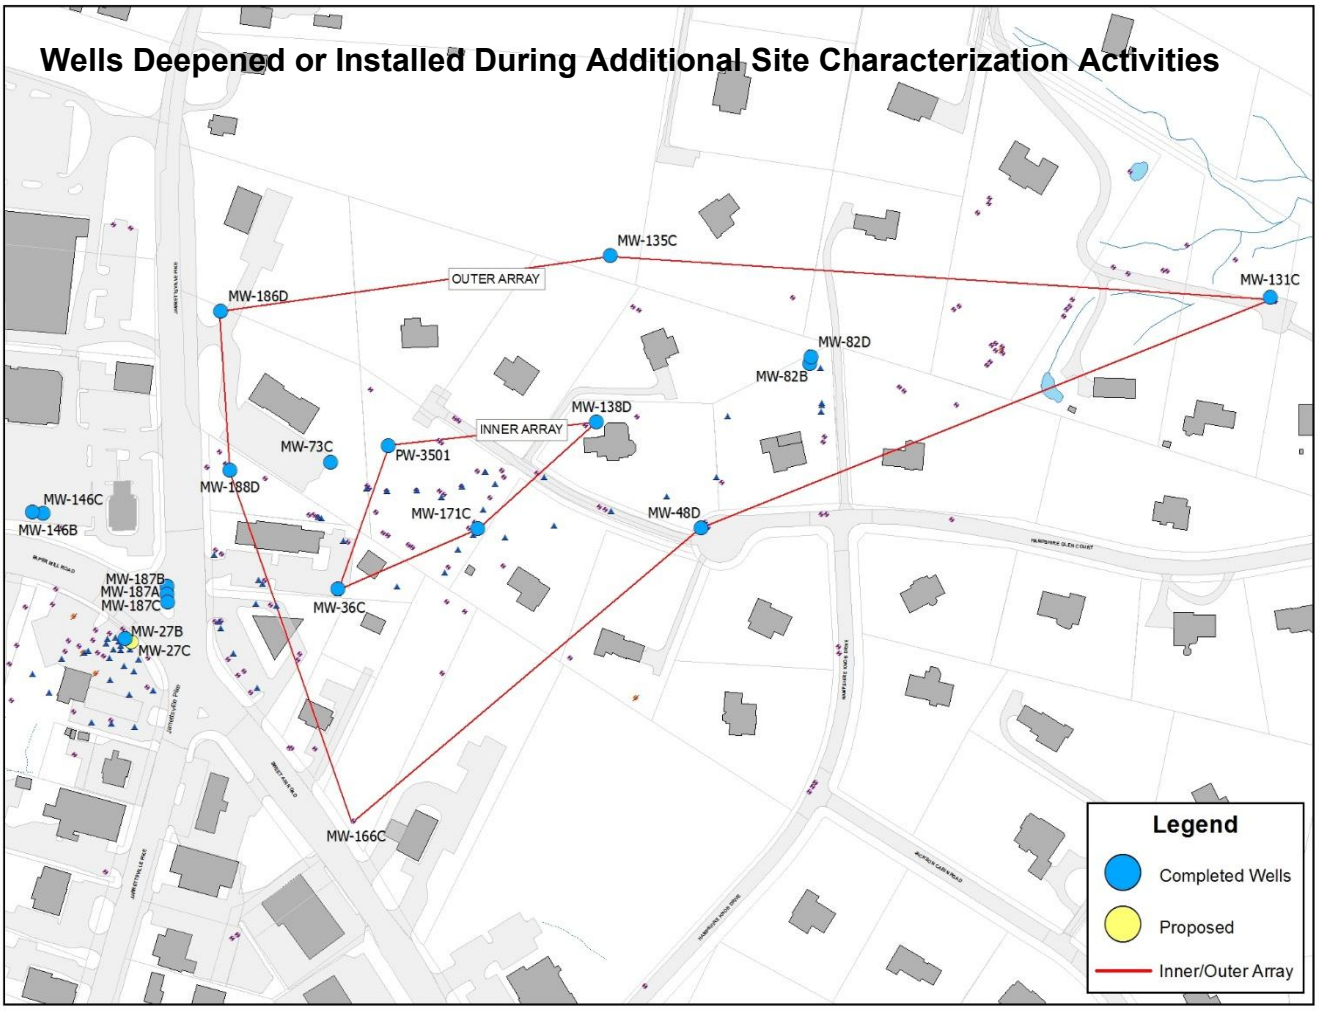
KLEINFELDER 1745 Dorsey Road, Suite J, Hanover, MD 21076 p | 410.850.0404 f | 410.850.0049



Additional Site Characterization

In June 2012, ExxonMobil submitted a work plan to install and/or deepen 17 monitoring wells with the following objectives (Kleinfelder 2012):

- Establish additional D zone monitoring points (greater than 300 feet bgs) in the near northeast area ("inner array");
- Encompass the near northeast area with additional D zone monitoring points to provide a sentinel array ("outer array");
- Provide supplemental characterization data beneath, along strike and down dip of the original release area on the former service station property and within relatively close proximity.

© 2026 Kleinfelder

Ultimately, 16 of the proposed wells were installed, excluding only MW-27C on the station property, which was deemed unnecessary, given concentrations in monitoring well MW-27B delineated the vertical extent of gasoline constituents. Downhole geophysical logging was completed on all installed and deepened wells in the "D" zone. Eleven wells were completed between July and December 2013; five were completed between March and May 2014. Two additional wells (MW-82B and MW-82D) were proposed and installed in 2014 at 3508 Hampshire Glen Court to further characterize groundwater beyond the original "inner array," based on results from the FLUTe™ samples collected from MW-138D.

1.5 SUPPLEMENTAL INVESTIGATIONS

Lineament Trace Analysis - 2007

In 2007, at the request of the MDE, a lineament trace analysis was completed to identify surface linear features, show possible relationships between the lineaments and known geological structure, and help identify potential structural features that could correlate to known regional hydrogeologic conditions. The lineament pattern primarily corresponds with the regional drainage patterns, oriented in a northeast/southwest pattern. Discrete interval sampling was proposed as a complimentary data set to better correlate the three-dimensional model of identified lineaments, fractures identified during downhole geophysical logging, and the distribution of dissolved-phase hydrocarbons (Kleinfelder 2008b).

Vertical Head Testing – 2011

In February 2011, ExxonMobil proposed a vertical head study to isolate vertical intervals of the bedrock aquifer and obtain potentiometric measurements. The study used clusters of "A," "B," and "C" zone wells, as well as the installation of packers to subdivide the open boreholes of various "C" zone wells. Work was conducted between April 11 and May 26, 2011 and reported to the MDE in September 2011 (Kleinfelder, 2011b). The data obtained from the vertical head study illustrated an upward hydraulic gradient beneath the northeast and southwest drainage valleys, and beneath the enhanced pumping remediation in the near northeast area. Downward hydraulic gradients were observed beneath the upland areas of the project. In general, the dominant vertical gradients between shallow and deep zones were consistent with what would be expected from elevated topography and from valley bottoms and surface drainage/streams (Kleinfelder 2011b).

APPENDIX B

SUMMARY OF REMEDIAL ACTIVITIES AND SYSTEM CHANGES

© 2026 Kleinfelder

APPENDIX B
SUMMARY OF REMEDIAL ACTIVITIES AND SYSTEM CHANGES

- February 17, 2006 – Onset of groundwater recovery activities using mobile remediation equipment.
- February 2006 to September 2006 – Temporary mobile groundwater recovery and treatment system; three SVE systems in the southwest quadrant - Flame Oxidizer 750, Bisco Dual Claw, and Bisco Liquid Ring Pump (LRP) DPE system; and, four SVE systems in the northeast quadrant - Flame Oxidizer 500, Airtech LRPs, MLE Claw 2, and ThermCat 500. Equipment operation and performance is detailed in the IRM Plan and Updated IRM Plan. Bisco LRP was shutdown in July 2006 and replaced with the MLE DPE Claw in August 2006, which extracts soil vapors and groundwater from the service station property extraction wells.
- October 2006 to March 2007 – Temporary groundwater treatment systems operated in the northeast quadrant; these were shutdown when the integrated groundwater treatment system was brought online.
- October 2006 to March 2008 – Temporary soil vapor extraction equipment was replaced with equipment designed for prolonged use at the site.
- February 5, 2007 – All recovered groundwater is treated on the service station property utilizing a combination of air stripping, a fluidized bed bioreactor, and liquid phase GAC.
- February 9, 2007 – ThermCat 500 (thermal oxidizer) was shutdown and was replaced by the Flame Oxidizer 500 SVE Blower extracting vapor from extraction wells in the northeast quadrant on 14307 Jarrettsville Pike, 3501 Hampshire Glen Court, and 3506 Hampshire Glen Court.
- February 9, 2007 – ESD Dual Claw SVE system was brought online, operating on wells formerly operated by the Flame Oxidizer 500 SVE Blower, extracting vapor from extraction wells in the northeast quadrant on 14301 Jarrettsville Pike and 14307 Jarrettsville Pike.
- May 31, 2007 – Temporary DPE system, Airtech LRPs (located on the Sweet Air Road property in the northeast quadrant) was shutdown, and replaced with the Bisco LRP DPE system (formerly used on the Service Station Property), extracting vapor and groundwater from extraction wells on 14307 Jarrettsville Pike and 3503 Hampshire Glen Court.
- May 31, 2007 – Flame Oxidizer 500 vapor treatment unit was shutdown (SVE Blower still operated) because soil vapor is below SVE general permit discharge limits and the vapors are now directed through vapor phase GAC prior to discharge to the atmosphere.
- May 31, 2007 – Flame Oxidizer 750 vapor treatment unit was shutdown (SVE Blower still operated) because soil vapors are below SVE general permit discharge limits and the vapors are now directed through vapor phase GAC prior to discharge to the atmosphere.
- August 9, 2007 – The Bisco LRP was relocated from 3410 Sweet Air Road to 3418 Sweet Air Road (northeast quadrant).
- August 10, 2007 – Flame Oxidizer 500 was taken offline, and transported offsite.

© 2026 Kleinfelder

KLEINFELDER 1745 Dorsey Road, Suite J, Hanover, MD 21076 p | 410.850.0404 f | 410.850.0049

- August 10, 2007 – ESD Dual Claw Skid I was brought online to replace the Flame Oxidizer 500, extracting vapors from the extraction wells in the northeast quadrant on 14307 Jarrettsville Pike, 3501 Hampshire Glen Court, and 3506 Hampshire Glen Court and treating the vapors with vapor phase GAC.
- October 4, 2007 – Flame Oxidizer 750 was taken offline and transported offsite. Piping retrofit and installation of the ESD Tri-Lobe was initiated in the former Flame Oxidizer 750 area.
- October 12, 2007 – Bisco LRP was taken offline due to liquid ring pump failure, SVE wells operated by the Bisco LRP were re-directed to the ESD Dual Claw and ESD Dual Claw Skid I, and pneumatic pumps were added to MW-36, MW-74, and MW-75.
- October 31, 2007 – ESD Tri-Lobe SVE system was brought online to replace the Flame Oxidizer 750, extracting vapors from extraction wells on the service station property and treating vapors with vapor phase GAC.
- February 18, 2008 – MLE Claw 2 was taken offline and transported offsite, extracted vapors were temporarily re-directed to the ESD Dual Claw Skid I while installation of replacement system was initiated.
- March 11, 2008 – Northeast Bisco Dual Claw was brought online to replace the MLE Claw 2 (located on the 3508 Hampshire Glen Court property), extracting vapors from extraction wells on 3506, 3508, and 3600 Hampshire Glen Court, and treating vapors with vapor phase GAC on 3418 Sweet Air Road.
- March 31, 2008 – New recovery wells, MW-16R and MW-27R, were connected to the groundwater remediation system and brought online for both groundwater extraction using pneumatic pumps (GWP&T) and soil vapor extraction (SVE).
- May 7, 2008 – Two SW groundwater storage fractionating tanks were transported offsite.
- May 12, 2008 – New air compressor installed, Plant Air Compressor, supplying air to all SW and NE pneumatic pumps. Former air compressors remain in place as back-ups.
- June 10, 2008 – Effluent groundwater fractionating tank (T702) emptied into effluent fractionating tank (T701) and transported offsite.
- June 17, 2008 – Monitoring well MW-89 was brought online for both GWP&T and SVE.
- August 13, 2008 – Monitoring well MW-121 was connected to the groundwater remediation system and brought online for both GWP&T and SVE.
- September 10, 2008 – Monitoring well MW-45R was connected to the groundwater remediation system and brought online for both GWP&T and SVE.
- January 19-23, 2009 – Three SVE pilot test wells were installed on the service station property to further evaluate onsite SVE recovery in the former UST field area.
- February 6, 2009 – New air compressor installed as a back-up to the Plant Air Compressor; capable of supplying air to all SW and NE pneumatic pumps
- March 3, 2009 – Recovery well MW-36 converted from DPE to GWP&T and SVE.
- April 17, 2009 – Monitoring well MW-58R was connected to the groundwater remediation system and brought online for both GWP&T (NE02 Zone) and SVE (ESD Dual Claw Skid). Groundwater recovery and soil vapor extraction was re-started on MW-38.

© 2026 Kleinfelder

- May 26, 2009 – Monitoring wells, MW-169, MW-170, and MW-171 were connected to the groundwater remediation system and brought online for both GWP&T (NE01) and SVE (ESD Dual Claw Skid).
- November 11, 2009 – Bisco Dual Claw SVE system permanently taken offline.
- November 13, 2009 – Recovery well, SVE-3, was transitioned to all-season below grade piping and reconnected to the groundwater recovery system.
- December 15, 2009 – Recovery wells, MW-78R and MW-100B, were taken offline for GWP&T. Northeast Bisco Dual SVE system permanently taken offline.
- February 18, 2010 – Recovery well, MW-34, was taken offline for GWP&T.
- March 17, 2010 – Recovery well, MW-33, was taken offline for GWP&T.
- April 19, 2010 – Recovery well, MW-51, was taken offline for GWP&T.
- May 24, 2010 – Recovery well, MW-124, was taken offline for GWP&T.
- May 28, 2010 – Monitoring well MW-91C was connected to the groundwater remediation system using temporary above grade piping; and brought online for GWP&T.
- June 1, 2010 – Monitoring well MW-54 was connected to the groundwater remediation system using temporary below grade piping; and brought online for GWP&T.
- June 22, 2010 – Recovery well MW-71 was taken offline for GWP&T.
- July 7, 2010 – Monitoring well SVE-1 was connected to the groundwater remediation system using temporary above grade piping; and brought online for GWP&T.
- September 20, 2010 – Begin LGAC-only treatment for low-concentration groundwater stream. Air stripper is maintained onsite.
- September 25, 2010 – Recovery well MW-54 was transitioned to all-season below grade piping.
- September 29, 2010 – Monitoring well MW-176 was connected to the groundwater remediation system using temporary above grade piping; and brought online for GWP&T.
- December 2, 2010 – Recovery wells MW-91C, MW-176, and SVE-1 were transitioned to all-season below grade piping.
- December 28, 2010 – Monitoring well MW-36R was connected to the groundwater remediation system and brought online for GWP&T. Recovery well MW-36 was taken offline for GWP&T.
- December 29, 2010 – Monitoring well MW-178C was connected to the groundwater remediation system and brought online for GWP&T.
- May 20, 2011 – Recovery well MW-28 was taken offline for GWP&T.
- June 15, 2011 – Recovery well MW-111 was taken offline for GWP&T.
- July 15, 2011 – Recovery well MW-102 was taken offline for GWP&T.
- August 15, 2011 – Recovery well MW-123 was taken offline for GWP&T.
- September 15, 2011 – Recovery well MW-113 was taken offline for GWP&T.
- October 12, 2011 – Recovery well MW-60 was taken offline for GWP&T.
- April 24, 2012 – Pneumatic pump in recovery well MW-171 identified as not operating properly and lodged in place inside the well borehole. Currently being used for monitoring only and “grab” sampling.

© 2026 Kleinfelder

- May 15, 2012 – Monitoring well MW-54B was connected to the groundwater remediation system and brought online for GWP&T.
- June 20, 2012 – Monitoring well MW-139 was connected to the groundwater remediation system and brought online for GWP&T.
- July 20, 2012 – Monitoring well MW-181B was connected to the groundwater remediation system and brought online for GWP&T.
- July 31, 2012 – Monitoring wells MW-183, MW-184, and MW-185 were connected to the groundwater remediation system and brought online for GWP&T.
- August 31, 2012 – ESD TriLobe SVE system taken offline due to high temperature.
- September 6, 2012 – ESD TriLobe SVE system repaired and resumed operations.
- September 20, 2012 – Monitoring well MW-38C was connected to the groundwater remediation system and brought online for GWP&T.
- August 21, 2013 – Exposed piping was removed from a stream bed in southwest in accordance with MDE approved work plan.
- September 17, 2013 – Monitoring well SVE-2 was connected and activated to the groundwater remediation system using temporary above grade piping.
- October 2, 2013 – Soil vapor extraction initiated at SVE-2.
- October 10, 2013 – ESD Dual Claw Trailer and ESD Dual Claw Skid I SVE systems permanently taken offline.
- November 19, 2013 – Temporary groundwater recovery and soil vapor extraction was ceased at SVE-2 following completion of a two-month evaluation period using above grade piping.
- November 19, 2013 – Recovery wells MW-25 and MW-80A taken offline for GWP&T.
- December 13, 2013 – Recovery wells MW-80B and MW-109 taken offline for GWP&T.
- January 16, 2014 – Recovery well MW-31 was taken offline for GWP&T.
- February 12, 2014 – Recovery well MW-49 was taken offline for GWP&T.
- March 12, 2014 – Recovery well MW-119 was taken offline for GWP&T.
- April 11, 2014 – Recovery wells MW-55 and MW-112 were taken offline for GWP&T.
- May 12, 2014 – Recovery well MW-117 was taken offline for GWP&T.
- May 13, 2014 – MLE DPE Claw system permanently taken offline.
- June 18, 2014 – ESD DPE Claw system (former ESD Dual Claw Trailer in the Northeast) was brought online as a replacement for MLE DPE Claw.
- June 20, 2014 – Monitoring well SVE-2 was connected to the groundwater remediation system with all-weather below-grade piping, and brought online for GWP&T and SVE.
- September 22, 2014 – Monitoring well MW-82B was connected to the groundwater remediation system with all-weather below-grade piping, and brought online for GWP&T.
- November 3, 2014 – Monitoring well MW-187B was connected to the groundwater remediation system with all-weather below-grade piping, and brought online for GWP&T.
- March 25, 2015 – Monitoring well MW-187A was connected to the groundwater remediation system with all-weather below-grade piping, and brought online for GWP&T.

© 2026 Kleinfelder

- April 14, 2015 – Bioreactor taken offline, subsequently approved for decommissioning on June 16, 2015.
- May 6, 2015 – Recovery wells MW-24, MW-26, MW-29, MW-30, MW-35, MW-52, and MW-154 were taken offline for GWP&T.
- June 15, 2015 – Soil vapor extraction initiated at MW-187A.
- July 21, 2015 – Electric pump in monitoring well MW-82B replaced with pneumatic pump.
- August 11, 2015 – Soil vapor extraction initiated at MW-187B.
- August 31, 2015 – Recovery wells MW-40, MW-72, MW-116, MW-118, MW-126, MW-127, and MW-156 were taken offline for GWP&T.
- September 18, 2015 – Soil vapor extraction discontinued from MW-187A.
- September 21, 2015 – Removal of FLUTe™ liner from MW-78C.
- May 11, 2016 – Soil vapor extraction resumed at MW-187A.
- May 18, 2016 – well MW-151 was taken offline for GWP&T.
- June 6, 2016 – Begin carbon only treatment for all groundwater recovery zones.
- July 26, 2016 – Install new HDPE underground piping and valve manifolds within subsurface vaults to permanently bypass the above-grade groundwater processing and storage equipment located in the northeast. Permanently remove northeast lift station, northeast tank 201, and northeast manifold room from GWP&T operation.
- October 27, 2016 – Remove offline LGAC vessels from NE remediation section.
- December 7, 2016 – Recovery well MW-32 converted to a monitoring well only after the water return line failed due to corrosion.
- December 2016 – Remove remaining above-grade equipment and components from the NE remediation section.
- April 12, 2017 – Tri-Lobe SVE system taken offline indefinitely; SVE wells MW-7, MW-16R, MW-27R, MW-187A and MW-187B connected to the ESD DPE law system.
- June 23, 2017 – Pump removed from MW-139 to replace non-functioning pump in MW-187B.
- September 19, 2017 – Pneumatic pump installed in MW-168 for temporary pump test, running off of air supply and water return from the MW-169 vault.
- October 10, 2017 – Pumps in recovery wells MW-178C and MW-183 were lowered an additional 50 feet to a total depth of 200 feet below grade.
- October 23 and 24, 2017 – Recovery well MW-181B was converted into a monitoring well. Monitoring well MW-181A was converted into a recovery well.
- December 29, 2017 – Pump and temporary above-grade piping connections removed from MW-168, terminating temporary pumping test.
- February 26, 2018 – One of the southwest influent tanks (T-102) was removed from site, all influent (untreated water) is now stored in remaining tank T-202.
- April 16, 2018 – Pneumatic pump reinstalled in MW-168, to continue pumping test longer-term.
- July 30, 2018 – MW-59D converted into a monitoring well as part of the MDE-approved Northeast sequential recovery well conversion. MW-151 pump removed from service.
- August 3, 2018 – MW-59B pump removed from service, MW-59D redeveloped.

© 2026 Kleinfelder

- August 13, 2018 – Recovery well MW-57 converted into a monitoring well as part of the MDE-approved Northeast sequential recovery well conversion. Other wells approved for conversion had pumps removed as previously reported, including MW-181B removed on 10/23/17, MW-76 removed on 5/21/18, MW-59D removed on 7/30/18, MW-32 removed 12/7/17, and MW-43A removed on 1/31/13.
- August 30, 2018 – MW-59B pump reinstalled.
- September 11, 2018 – Subterranean leak was identified at location of abandoned well MW-51. Air turned off to southwest zones A-E.
- September 12 through 13, 2018 – Recovery wells MW-110, MW-85, MW-77A were converted into monitoring wells and redeveloped as part of the MDE-approved Northeast sequential recovery well conversion. Also scheduled for monitoring well conversion in September was MW-58, although the pump for MW-58 had already been removed on 3/28/18 due to the pump not functioning properly.
- September 27, 2018 – Pump and temporary above-grade piping connections removed from MW-168, terminating temporary pumping test.
- October 8, 2018 – Recovery wells MW-36R, MW-77R, MW-87, and MW-137 were converted into monitoring wells and redeveloped as part of the MDE-approved Northeast sequential recovery well conversion.
- October 16, 2018 – Pump installed in MW-187C to a depth of 150’ bgs.
- October 26, 2018 – Pumps were removed from MW-9 and MW-17.
- November 6, 2018 – Recovery well MW-77B was converted into a monitoring well and redeveloped as part of the MDE-approved Northeast sequential recovery well conversion.
- November 7, 2018 – Recovery wells MW-58R, MW-82, and MW-84 were converted into monitoring wells and redeveloped as part of the MDE-approved Northeast sequential recovery well conversion.
- December 5, 2018 – MW-188D Packer removed and purged of 275 gallons.
- December 5 through 20, 2018 – New remediation system components (influent tank T-100, effluent tank T-200, transfer pumps and totalizers) installed in former service bay area and tested.
- January 3, 2019 – Commissioning of new groundwater treatment system results in all recovered water being treated through new influent/effluent tanks, transfer pumps and totalizers.
- January 18, 2019 – Former influent and effluent frac tanks dewatered and fully removed from service.
- February 11, 2019 – Former discharge trailer and southwest lift station decommissioned and removed from the site.
- March 5, 2019 – Recovery well pump in MW-54B deepened to 115’ below top of casing and recovery well pump in MW-38C deepened to 150’ below top of casing with MDE approval.
- April 8, 2019 – Recovery well pump installed to 150’ below top of casing in MW-138D and connected to the recovery network.
- April 26, 2019 – Recovery wells MW-169 and MW-185 were converted into monitoring wells and redeveloped as part of the MDE-approved Northeast sequential recovery well conversion.

© 2026 Kleinfelder

- May 3, 2019 – Recovery well pump installed to 150' below top of casing in MW-82D.
- May 10, 2019 – Recovery well pump installed to 150' below top of casing in MW-73C; temporary above-ground piping connections were made to the vault in MW-178C for on-going pump test.
- May 22 through June 5, 2019 – A total of 48 monitoring wells were abandoned in accordance with the MDE-approved *Groundwater Monitoring Reduction and Well Abandonment Request* submitted on January 22, 2019.
- June 10 through 12, 2019 – Recovery wells MW-1A, MW-6, MW-91C, and MW-152 were converted to monitoring wells and redeveloped as part of the MDE-approved sequential recovery well conversion.
- July 8 through 12, 2019 – Recovery wells MW-22 and MW-74 were converted to monitoring wells and redeveloped as part of the MDE-approved sequential recovery well conversion.
- July 30 through 31, 2019 – Recovery wells MW-21, MW-2A, and MW-38 were converted to monitoring wells and redeveloped as part of the MDE-approved sequential recovery well conversion.
- October 1 through 2, 2019 – Recovery wells MW-19, MW-23, MW-75, and MW-170 were converted to monitoring wells and redeveloped as part of the MDE-approved sequential recovery well conversion.
- October 29, 2019 – MW-138D and MW-187C were lowered 20' to increase groundwater recovery.
- November 5, 2019 – MW-73C pump taken offline in advance of winter and rebound testing. Sparge device installed to depth of 150' in MW-91C to test potential remedial effectiveness in bedrock aquifer.
- March 10, 2020 – Recovery well pump installed to 150' below top of casing in MW-73C; temporary above-ground piping connections were made to the vault in MW-178C for on-going pump test.
- April 20, 2020 – Sparge device removed from MW-91C upon conclusion of six month test period.
- April 28, 2020 – SVE/DPE system taken offline after receiving approval from the MDE.
- May 5, 2020 – Former DPE wells MW-3, MW-13, and MW-27 were converted into pneumatic recovery wells. Pneumatic recovery well MW-4 taken offline, with its pump being used to initiate recovery in MW-3. Monitoring well MW-16 was converted into a pneumatic recovery well.
- June 30, 2020 – Recovery wells MW-37, MW-82R, and MW-89 were converted to monitoring wells and redeveloped as part of the MDE-approved sequential recovery well conversion.
- July 1, 2020 – Recovery wells MW-27R and MW-121 were taken offline as part of the MDE-approved sequential recovery well conversion.
- July 21 to July 23, 2020 – Monitoring wells MW-30P, MW-34P, MW-36P, MW-37P, MW-38P, MW-45P, MW-57P, MW-58P, MW-58R, MW-63, MW-76P, MW-85P, MW-103, MW-119, MW-122, MW-130, MW-132A, MW-134A, MW-134B, MW-136, MW-142, MW-145P, MW-150A, MW-156 and MW-157P were abandoned as part of the MDE-approved monitoring well reduction and abandonment plan.
- July 23, 2020 – Recovery well MW-183 depth of pump changed from 200 feet below grade to 150 feet below grade per MDE request.

KLEINFELDER 1745 Dorsey Road, Suite J, Hanover, MD 21076 p | 410.850.0404 f | 410.850.0049

- July 27, 2020 – Monitoring wells MW-84P, MW-86, MW-87P and MW-104 were abandoned as part of the MDE-approved monitoring well reduction and abandonment plan.
- August 3 to August 5, 2020 – Recovery wells MW-7, MW-13, MW-59B, MW-82B, MW-151, MW-176, MW-184 and SVE-2 were taken offline as part of the MDE-approved sequential recovery well conversions.
- December 15, 2020 – Recovery well MW-73C pump taken offline in advance of winter.
- March 29, 2021 – Recovery well MW-73C pump taken online after winter.
- June 28, to June 30, 2021 – Recovery wells MW-16, MW-27, MW-54B, MW-82D, and MW-181A were taken offline as part of an MDE-approved sequential recovery well conversion.
- March 11, 2022 – Groundwater pump and treat system taken offline for the Recovery Well Cycling test.
- May 27, 2022 – Groundwater pump and treat system brought online for a two week period.
- June 8, 2022 – Groundwater pump and treat system taken offline to resume the Recovery Well Cycling test.
- August 31, 2022 – Recovery pumps reinstalled, however the system compressor was non-functional and the groundwater recovery system remained offline.
- October 20, 2022 – New compressor installed and system restarted. Groundwater pump and treat system resumed operation with recovery wells at MW-187A, MW-187C, and MW-178C online.
- November 21, 2022 – Groundwater pump and treat system taken offline to continue cycling test.
- December 9, 2022 – Groundwater pump and treat system brought back online with MW-187A, MW-187C and MW-178C operational.
- January 10, 2023 – Recovery well MW-54B brought back online.
- January 27, 2023 – Recovery well MW-178C was taken offline and pump removed. Pump reinstalled in recovery well MW-38C and brought back online.
- February 28, 2023 – Groundwater pump and treat system taken offline to begin cycling test.
- March 27, 2023 – Groundwater pump and treat system taken online to continue cycling test.
- April 28, 2023 – Groundwater pump and treat system taken offline to continue cycling test.
- June 1, 2023 – Groundwater pump and treat system taken online to conclude cycling test.
- July 18, 2023 – Influent groundwater redirected to avoid blockage, bypassing influent totalizers.
- December 21, 2023 – Groundwater pump and treat system taken offline.

APPENDIX C

Monitoring Well Construction and Activity Summary
Inactive Exxon Facility #28077
14258 Jarrettsville Pike
Phoenix, Maryland

First Quarter 2026

Well ID	Borehole Diameter (inch)	Well Diameter (inch)	Riser/ Casing Length (feet)	Screen Length/ Open Interval (feet)	Total Borehole Depth (feet)	Screen Interval (feet below TOC)	TOC Elevation	Address	Comment

TOC = Top of Casing
BTOC = Below Top of Casing
DPE = Dual Phase Extraction

SVE = Soil Vapor Extraction
NSVD = Not Surveyed to Vertical Datum

* = Well Abandoned
fbg = feet below grade
NE = Not Encountered

FLUTe liners were installed into the following wells:

- MW-41C (sample ports at 75-80 fbg, 95-97 fbg, 120-130 fbg, 190-195 fbg) FLUTe liner was removed on May 7, 2024

- MW-53C (sample ports at 215-220 fbg and 225-235 fbg) FLUTe liner was removed on May 8, 2024

- MW-56C (sample ports at 100-110 fbg, 310-315 fbg, 320-325 fbg) FLUTe liner was removed on March 26, 2024

- MW-78C (sample port at 60-70 fbg). FLUTe liner was removed on September 21, 2015

- MW-138D (sample port at 77-82 fbg, 95-100 fbg, 120-125 fbg, 151-156 fbg, 190-200 fbg, 217-222 fbg, 250-255 fbg, 288-293 fbg, 332-337 fbg, 379-384 fbg).

MONITORING WELL BORING AND CONSTRUCTION LOGS

© 2026 Kleinfelder

LOG OF MONITORING WELL NO. MW-01

Project Description: **Exxon RAS # 2-8077**
Location: 14250 Jarrettsville Pike - Phoenix, MD
Permit Number: BA-95-0510
T.O.C.: 93.0 ft Static Water Level: 34.1 ft

Completion Depth:	44.9 ft.
Date Boring Started:	7/22/05
Date Boring Completed:	7/22/05
Engineer / Geologist:	CAS
Project No.:	60507606

Remarks: Bottom of well at 44.9 feet.
Driller: BL Myers
Drill Method: Air Rotary
Sample Method: Core Barrel

KLEINFELDER

The stratification lines represent approximate strata boundaries. In situ, the transition may be gradual

LOG OF MONITORING WELL NO. MW-04

Project Description: **Exxon RAS # 2-8077**
Location: 14250 Jarrettsville Pike - Phoenix, MD
Permit Number: BA-95-0513
T.O.C.: 95.2 ft Static Water Level: 33.6 ft

Completion Depth: 49 9 ft
Date Boring Started: 7/22/05
Date Boring Completed: 7/22/05
Engineer / Geologist: CAS
Project No.: 60507606

Remarks: Bottom of well at 49 9 feet
Driller: BL Myers
Drill Method: Air Rotary
Sample Method: Core Barrel

KLEINFELDER

The stratification lines represent approximate strata boundaries. In situ, the transition may be gradual.

Client: ExxonMobil Refining and Supply Company
Drilling Company: B.L. Myers
Driller: Ray Chilcote
Drill Rig Type: Air Rotary
Drilling Method: Air Rotary
Sampling Method: NS

Start Date: February 23, 2006
End Date: February 23, 2006
Total Hole Depth: 46 feet
Hole Diameter: 10 inches
Depth to Bedrock: 36.5 feet
Surface Elevation: 101.81 feet
Water Level (Initial): NM
Water Level (Static): NM
Logged By (Geol.): Dan Raines

Permit No.:
License No.:
Checked By:
Notes: Hand cleared to 8 feet using air knife and vacuum. Core sample from 36.5 to 46 fbg

Drilling Company: BL Myers
Driller: Stephen Saul
Drill Rig Type: Atlas CapCo T4
Drilling Method: Air Rotary
Sampling Method:

Start Date: 10-5-10
End Date: 10-20-10
Total Hole Depth: 125 feet
Hole Diameter: 6 - 10 inches
Depth to Bedrock: 39 feet
Surface Elevation: 587.65 ft./msl.
Water Level (Initial): Not Encountered
Water Level (Static): Not Encountered
Logged By (Geol.): J. Beck

Permit No.: BA-95-3568
License No.: MWD421
Checked By: K. Braun
Notes: Airknife to 8 feet

BORING LOG
Boring No. MW-91D

Project Name: Inactive Exxon Facility #28077
Site Location: 14258 Jarrettsville Pike, Phoenix, Maryland
Kleinfelder Project No: 108818
Client: ExxonMobil
Drilling Company: BL Myers
Driller: Stephen Saul
Drill Rig Type: Atlas CapCo T3
Drilling Method: Air Rotary
Sampling Method: NA

Start Date: 10-5-10
End Date: 10-28-10
Total Hole Depth: 420'
Hole Diameter: 6 - 10 - 15 inches
Depth to Bedrock: 45 feet
Surface Elevation: 586.76 ft./msl.
Water Level (Initial):
Water Level (Static):
Logged By (Geol.): W. Willow, J. Beck

Permit No.: BA-95-3567
License No.: MWD421
Checked By: K. Braun
Notes: Airknife to 8 feet

DRILLING LOG
Well No. MW-111

Project Name: Exxon #28077
Site Location: 14258 Jarrettsville Pike, Phoenix, MD
GSC|KA Project No: 60507606
Client: ExxonMobil Refining and Supply Company
Drilling Company: B.L. Myers
Driller: Joe Griffin
Drill Rig Type: Air Rotary
Drilling Method: Air Rotary
Sampling Method: NS

Start Date: March 30, 2006
End Date: March 30, 2006
Total Hole Depth: 50 feet
Hole Diameter: 12 inches
Depth to Bedrock: 10 feet
Surface Elevation: NM
Water Level (Initial): 25.5 feet below grade
Water Level (Static): NM
Logged By (Geol.): Jamie Stapleton

Permit No.:
License No.:
Checked By:
Notes: Hand-cleared to 8 feet below grade.

Project Name: Exxon #28077
Site Location: 14258 Jarrettsville Pike, Phoenix, MD
GSC|KA Project No: 60507606
Client: ExxonMobil Refining and Supply Company
Drilling Company: B.L. Myers
Driller: Joe Griffin
Drill Rig Type: Shramm Air Rotary
Drilling Method: Air Rotary
Sampling Method: NS

Start Date: April 3, 2006
End Date: April 3, 2006
Total Hole Depth: 53 feet
Hole Diameter: 10 inches
Depth to Bedrock: 23 feet
Surface Elevation: NM
Water Level (Initial): 30.5 fbg
Water Level (Static): NM
Logged By (Geol.): Steven Treschow

Permit No.:
License No.:
Checked By:
Notes: Hand-cleared to 5 feet below grade.

Well No. MW-131C

Project Name: Inactive Exxon Facility # 28077
Site Location: 14258 Jarrettsville Pike
Kleinfelder Project No: 138681
Client: ExxonMobil
Drilling Company: BL Myers Bros./Eichelbergers
Driller: Matt Disley/Jerry Books
Drill Rig Type: IR T3W/IR T4W
Drilling Method: Air Rotary
Sampling Method: Cuttings

Start Date: 01/23/2008
End Date: 10/08/2013
Total Hole Depth: 359'
Hole Diameter: 6"
Depth to Bedrock: 36'
Top-Of-Casing Elevation: TBD
Water Level (Initial): ~10'
Water Level (Static): 9'
Logged By (Geol.): TMK/JM

Permit No.: BA-95-2076
License No.: JWD351
Checked By: EW/JM
Notes: Well was initially drilled to 300' bgs on 01/23-25/2008 and deepened to 359' bgs on 10/08/2013.

Client: ExxonMobil
Drilling Company: B.L. Myers
Driller:
Drill Rig Type: Air Rotary
Drilling Method: Air Rotary
Sampling Method: NS

Start Date: April 19, 2006
End Date: April 19, 2006
Total Hole Depth: 80 feet
Hole Diameter: 10 inches
Depth to Bedrock: 27 feet
Well Diameter: 6 inches
Water Level (Initial): 64 feet
Screen Length: 20 feet
TOC Elevation: 592.43

Logged By (Geol.): Pat Donahue
Permit No.: BA-95-1258
Checked By: E. Henry
Notes: Well was installed within an existing, corrugated steel casing.

BORING LOG

Boring No. MW-174C

Project Name: Inactive Exxon Facility # 28077
Site Location: 14258 Jarrettsville Pike, Phoenix, MD
Kleinfelder Project No: 100891
Client: Exxon Mobil Environmental Services
Drilling Company: Eichelbergers
Driller: T. Toland
Drill Rig Type: Schramm T555
Drilling Method: Air Rotary
Sampling Method: Grab

Start Date: 12-7-09
End Date: 12-8-09
Total Hole Depth: 300 feet
Hole Diameter: 0'-60' -10"/ 60'-300' -6"
Depth to Bedrock: 14 feet
Surface Elevation: NSVD
Water Level (Initial): 18 feet
Water Level (Static): 11.89 feet
Logged By (Geol.): K. Braun

Permit No.: BA-95-3213
License No.: NA
Checked By: J. Hale
Notes: Airknife to 4 feet

SUBSURFACE PROFILE			SAMPLE

Site Location: 14258 Jarrettsville Pike, Phoenix, MD
Kleinfelder Project No: 138681
Client: ExxonMobil
Drilling Company: Eichelbergers
Driller: Carey Knaub
Drill Rig Type: Ingersoll-Rand T4W
Drilling Method: Air Rotary
Sampling Method: Hand Auger/Cuttings

Start Date: 04/28/2014
End Date: 05/15/2014
Total Hole Depth: 300'
Hole Diameter: 6-12"
Depth to Bedrock: 43'
Top-Of-Casing Elevation: TBD
Water Level (Initial): ~36.6'
Water Level (Static): NA
Logged By (Geol.): JM

Permit No.: BA-10-0627
License No.: JWD314
Checked By: JCM
Notes: Pre-cleared to 8' bgs
Well located at the intersection of Jarrettsville Pike and Paper Mill Road, Phoenix, MD

Soil Cuttings

Open Hole

The borehole was terminated at approximately 384 ft. below ground surface.

GROUNDWATER LEVEL INFORMATION:
▽ Groundwater was observed at approximately 10 ft. below ground surface during drilling.
GENERAL NOTES:
A PID (ppmv) was used for environmental field screening.

Well No. PW-3501

Project Name: Inactive Exxon Facility # 28077
Site Location: 14258 Jarrettsville Pike
Kleinfelder Project No: 138681
Client: ExxonMobil
Drilling Company: Unknown/Eichelbergers
Driller: Robert Brown/Carey Knaub
Drill Rig Type: Unknown/IR T4W
Drilling Method: Air Rotary
Sampling Method: Cuttings

Start Date: 02/29/1988
End Date: 07/19/2013
Total Hole Depth: 425'
Hole Diameter: 6"
Depth to Bedrock: NR
Top-Of-Casing Elevation: TBD
Water Level (Initial): NR
Water Level (Static): 45'
Logged By (Geol.): RB/JM

Permit No.: BA-81-7044
License No.: 399/JWD314
Checked By: JM
Notes: Well at 3501 Hampshire Glen Ct. Well initially drilled to 300' bgs on 02/29/1988 and deepened to 425' bgs on 07/16-19/2013.

Well No. SVE-3

Project Name:	*Inactive Exxon Facility # 28077*	*Start Date:*	*01-19-09*	*Logged By:*	*AW*
Site Location:	*14258 Jarrettsville Pike, Phoenix, MD*	*End Date:*	*01-21-09*	*Permit No.:*	*BA-95-2793*
Project No:	*100891*	*Total Hole Depth:*	*69 feet*	*Checked By:*	*MRN, JRH*
Client:	*ExxonMobil*	*Hole Diameter:*	*12" to 19', 10" to 69'*	*Notes:*	*Weathered bedrock at 12'*
Drilling Company:	*Eichelbergers*	*Depth to Bedrock:*	*19 feet*		*Air knifed to 5'*
Driller:	*T. Toland*	*Well Diameter:*	*6 inches*		
Drill Rig Type:	*2004 Schramm Model T450WS*	*Water Level (Initial):*	*63 feet*		
Drilling Method:	*Air Rotary*	*Screen Length:*	*45 feet*		
Sampling Method:	*Cuttings*	*TOC Elevation:*	*589.38*		

Depth (feet)	Graphic Log	Soil/Geologic Description	RQD %	PID Headspace (ppm)	Well Completion Details	Depth (feet)
55.0						55.0
60.0		**BR** GNEISS, dark gray, moist		0		60.0
65.0		**BR** GNEISS, dark gray, wet Terminated at 69.0 feet		0		65.0
70.0						70.0
75.0						75.0

PID - Photoionization Detector
ppm - Parts per million
NA - Not Applicable
* Sample submitted for laboratory analysis

- Water Level Initial Measurement
- Water Level Subsequent Measurement

Sample ID:
HA - Hand Auger Sample
S - Split Spoon Sample
GS - Grab Sample
C - Macrocore Sleeve

APPENDIX E

GROUNDWATER GAUGING DATA, 1Q 2006 – 1Q2026

APPENDIX E

Monitoring Well Gauging Data Summary
Inactive Exxon Facility #28077
14528 Jarrettsville Pike
Phoenix, Maryland

January 2, 2020 through March 17, 2026

Sample ID	Date	Top of Casing Elevation	Depth to Water (feet)	Depth to Hydro-carbon (feet)	Hydro-carbon Thickness (feet)	Corrected GW Elevation (feet)	Comments
SVE-3 [R]	09/08/2025	589.28	34.40	ND	ND	554.88	
	09/18/2025	589.28	34.22	ND	ND	555.06	
STREAM01	02/23/2022	NSVD	NM	NM	NM	NM	Not measured
STREAM02	03/28/2023	NSVD	0.00	ND	ND	NSVD	

Notes:
[R] - Indicates the well was used for remediation at the time of reporting.
GW - Groundwater
LPH - Liquid-phase hydrocarbon
N/A - Not applicable
ND - Not detected
NM - Not measured
NM - not monitored
NSVD - Not surveyed to vertical datum

Notes:
µg/L - micrograms per liter
AP - above packer
B - Compound was found in the blank and sample
BP - below packer
BRL - Below laboratory reporting limits
BTEX - Benzene, toluene, ethylbenzene, and total xylenes
cn - Refer to Case Narrative for further detail
DIPE - di-isopropyl ether
ETBE - ethyl tert butyl ether
F1 - MS and/or MSDrecovery exceeds control limits
F2 - MS/MSD RPD exceeds control limits
HS - Composite HydraSleeve
HS-D - deep composite HydraSleeve sampler; set at bottom of open borehole
HS-S - shallow composite HydraSleeve sampler; set at ½ of open borehole
J - Indicates an estimated value
MTBE - methyl tertiary butyl ether
NA - Not analyzed
ND(5.0) - Not detected at or above the laboratory reporting limit, laboratory reporting limit included.
NS - Not sampled
PW - Inactive supply well being used as a monitoring/sampling location
TAME - tert-amyl methyl ether
TBA - tert butyl alcohol

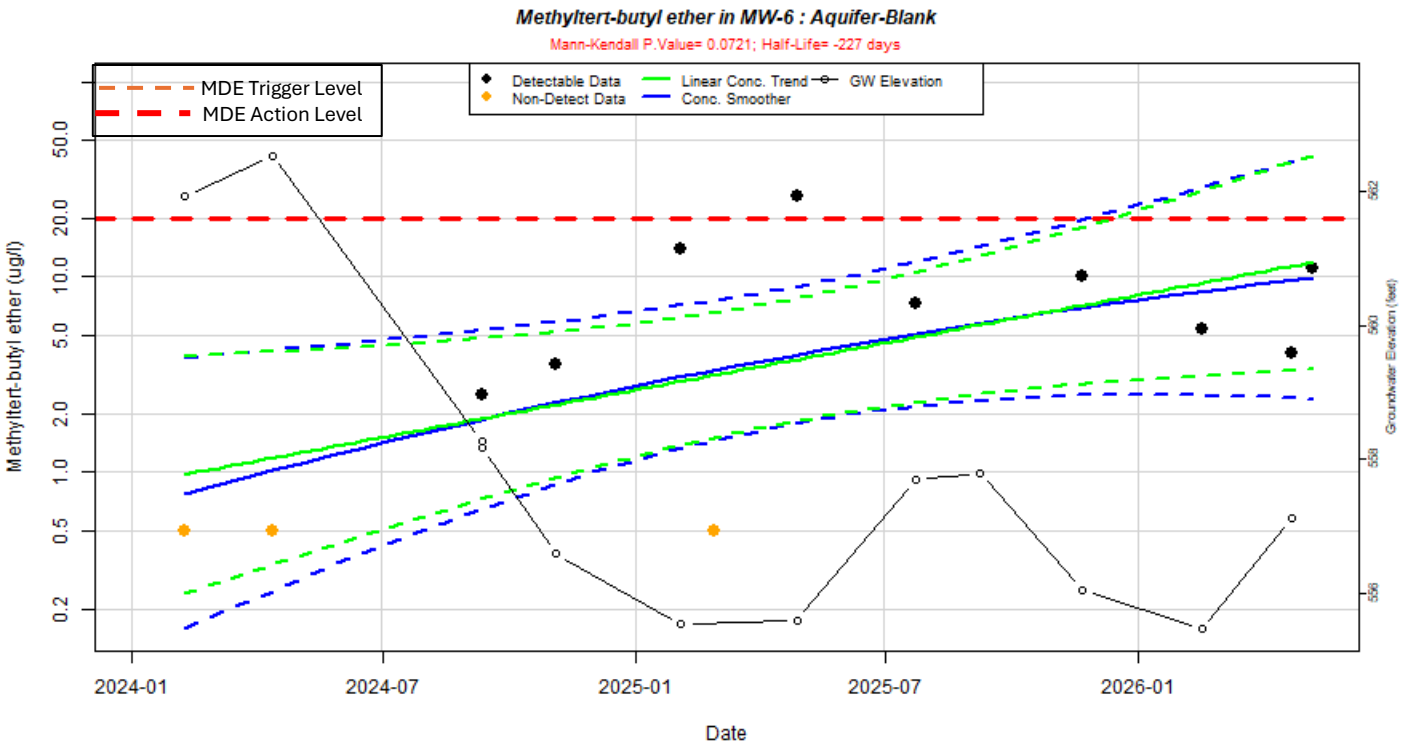
NOTES:



* Compounds which are also used by the laboratory and are considered artifacts
ND = Not detected; laboratory reporting limit in parentheses
PID = Photoionization detector
ppm = Parts per million
MTBE = Methyl tertiary butyl ether
TPH-GRO = Total Petroleum Hydrocarbons - Gasoline Range Organics
TPH-DRO = Total Petroleum Hydrocarbons - Diesel Range Organics
mg/kg = Milligrams per kilogram
µg/kg = Micrograms per kilogram
NA = Not applicable
PES = Post-Excavation Sample
